APPENDIX

1.0 INTRODUCTION

This Current Conditions Report (CCR) has been prepared by Advanced GeoServices Corp (Advanced GeoServices), on behalf of Exide Technologies (Exide) for the former battery manufacturing facility (the Facility) located at 555 North Hoke Avenue in Frankfort, Indiana (the Site). The Facility is located as shown on the attached Site Location Map (Figure 1).

Exide is the Respondent for a United States Environmental Protection Agency (USEPA) Administrative Order on Consent (Consent Order) under Section 3008(h) of the Solid Waste Disposal Act, commonly referred to as the Resource Conservation and Recovery Act of 1976 (RCRA), as amended by the Hazardous and Solid Waste Amendments of 1984, 42 USC 6928(h). The lead enforcement agency for the Site is the USEPA Region 5.

1.1 PURPOSE

As required by Section 11.a of the Consent Order, this CCR is being developed to compile and assess the information collected to date for the Site, describe the physical conditions and extent of contamination, and summarize the historic operations at the Site. The information presented in the CCR will be used to develop a RCRA Facility Investigation Work Plan (RFI Work Plan) as required by Section 11.b of the Consent Order.

1.2 REPORT ORGANIZATION

The CCR has been organized to present information on historic operations, current conditions, and concepts for future investigation and potential remediation. The Site contains several Solid Waste Management Units (SWMUs) and Areas of Concern (AOCs) which may have impacts from historic operations. These are further consolidated into larger Areas of Interest (AOIs) based on the historic Site operations and potential Contaminants of Concern (COCs) that have been identified or are potentially present.

The remainder of the CCR is organized as follows:

- Section 1.0 – Introduction
- Section 2.0 – Site Description
- Section 3.0 – Site History
- Section 4.0 – Environmental Setting
- Section 5.0 – Regulatory History
- Section 6.0 – Historic Investigations and Data
- Section 7.0 – Contaminants of Concern
- Section 8.0 – Conceptual Site Model
- Section 9.0 – Interim Corrective Measures Assessment
- Section 10.0 – Data Gaps
- Section 11.0 - References

Tables are provided to present information on the AOCs/AOIs as well as to summarize historic data. Figures are provided which depict the former Site layout, current conditions, and historic sample locations. Several appendices are also attached to provide the reader with detailed information that has been compiled for the Site such as laboratory reports, well search records, historic photographs, and other relevant records and documents.

2.0 SITE DESCRIPTION

The Site is located at 555 North Hoke Avenue in Frankfort, Indiana as shown on Figure 1 (based on USGS Topographic maps for *Michigantown Quadrangle and Frankfort Quadrangle, Indiana-Clinton County 7.5 minute series*). The Site is bounded by North Hoke Avenue to the west, Kelley Avenue to the east, Washington Street to the north, and Norfolk Southern railroad tracks to the south. The Site is located within Clinton County.

The majority of the Site corresponds to the tax parcel with the address 555 North Hoke Avenue. However, several other contiguous/adjacent parcels located along Washington Street and Kelley Avenue are also owned by Exide. Most of these lie within the existing perimeter fence.

For purposes of this report "the Site" will refer to all of the Exide owned parcels that are contiguous/adjacent to the 555 North Hoke Avenue parcel. The Site parcels are summarized on Table 1 and Figure 2.

These Site parcels encompass approximately 13.7 Acres. Approximately 4.5 acres of the Site, were formerly under roof for battery manufacturing and related operations. Approximately 12.1 acres of the Exide owned parcels are located within the perimeter of an existing security fence. No above grade structures remain onsite. Only floor slabs remain. The area within the fence is almost entirely paved. The remaining 1.6 acres of the Site lies outside of the fence and has an open grass covered surface.

An unnamed creek is adjacent to the Site on the north side of the Exide parcels. The coordinates for the facility are 40º 17′ 08″ N, 86º 29′ 45″ W. Residential properties are located on Hoke Avenue, Kelly Avenue, and south of the railroad tracks. Several light industrial and commercial properties are located near the Site on Washington Street.

The Site was formerly used for the manufacture of lead-acid batteries from 1963 – 1997 (and possibly as early as the 1940s), with manufacturing present at the Site dating back to the early 1900's. As a result of these operations a total of nine (9) SWMUs and three (3) AOCs are present onsite. The Site is categorized with four Areas of Interest (AOIs) based on historic use, current conditions, and recent investigations.

- Former Manufacturing Areas – This includes all of the former buildings/structures and ancillary equipment such as baghouses and water treatment equipment. This includes all nine (9) SWMUs and AOCs 1 and 2.
- Underground Storage Tanks – Records indicate that three Underground Storage Tanks (USTs) were present onsite at one time. These were generally located adjacent to the Former Manufacturing Areas on the northeast portion of the Site.
- Overall Site – this includes the remaining portions of the Site that were not utilized for manufacturing or USTs such as the majority of paved areas of the Site that were used for vehicle and truck parking and/or short term material storage.
- Groundwater – this includes the groundwater below the Exide-owned parcels.

3.0 SITE HISTORY

3.1 OWNERSHIP HISTORY

Limited information is available regarding the exact nature of historic manufacturing operations at the Site. Based on information contained in the Consent Order and a November 28, 2011 Letter Report prepared by USEPA, Prest-O-lite Manufacturing owned the Site during the World War II era. Prest-O-Lite was a car equipment manufacturer (including lead acid batteries), although this ownership history and specific Prest-O-Lite manufacturing operations conducted on-site could not be confirmed during preparation of this Current Conditions Report. Based on Polk's City Directory in 1959 a telephone exchange registered to P.R. Mallory & Co. Inc. was listed for the address. P.R. Mallory & Co. manufactured electronics including dry cell batteries and eventually became Duracell. General Battery Corporation purchased the Site in 1963, which is consistent with additional information from Polk's City Directory which shows the telephone exchange for the address belonging to General Battery & Ceramic Co. Exide assumed ownership of the Site during the acquisition of General Battery Corporation in 1988. Exide currently owns the parcels that make up the Site.

3.2 OPERATIONAL HISTORY

3.2.1 Early History

Carriage manufacturing operations reportedly began on the Site in the early 1900s. Historic aerial photographs dating back to 1969 show many structures that were still present at the time of demolition in 2012. Prior to 1963, the Site was also reportedly used for cabinet manufacturing. It is possible that Prest-O-Lite, P.R. Mallory and cabinet manufacturing operations all occurred on the property between World War II and 1963.

3.2.2 Battery Manufacturing

In 1963, General Battery Corporation began the manufacture of lead-acid batteries for use in automotive, golf cart, marine and industrial applications. At its peak the facility produced over 12,000 automotive batteries per day. The Standard Industry Classification (SIC) code for the facility was 3691, Battery manufacturing. The aerial photograph taken in 1969 shows a Facility layout that looks very similar in development to conditions observed in subsequent photographs. Notable exceptions are the pink coloration in the center of the northern portion of the facility (later developed as "New Formation") and in the parcels located along Kelley Avenue. The pink coloration on the aerial photograph is typically indicative of vegetation photographed by color-infrared (CIR) aerial photography.

The extent of paved areas is unclear in the 1977 aerial photo. The 1981 aerial photo (Appendix A) clearly shows that the remaining portions of the Site, along Kelley Avenue have been paved. The New Formation portion of the facility was constructed in the late 1980s or early 1990s and is visible in the 1992 aerial photograph (Appendix A). Some portions of the New Formation area may have been enclosed earlier in the 1980s.

During the battery manufacturing process, metallic lead was received at the facility, melted, and cast into grids and posts. Lead oxide paste was also manufactured at the facility and subsequently applied to the grids. Lead oxide was created by feeding molten lead into a reactor and mixing it with air to oxidize the lead. Pasted grids were placed in stacks that formed the core of the battery. The cores were placed in battery cases that were produced offsite. Then the remaining components were added. Electrolyte (dilute sulfuric acid) was then added to the battery and a charge was applied (formation). After formation, the battery was cleaned, finished, labelled, and packaged for shipment to retailers and distributors.

Water was used to cool batteries after charging and also to wash batteries prior to shipment. Cooling water was collected in floor drains and emptied to a sump in the wastewater treatment plant (WWTP) located on the northwest corner of the Site. The sump collected wastewater from the entire plant, including sulfuric acid from the cooling and washing process, and lead from

washing and dry charge operations. The corrosive wastewater (containing primarily sulfuric acid and lead) was pumped into two above ground holding tanks outside the building and then into reactor tanks located inside the WWTP building (SWMU-5).

Wastewater was treated with lime to neutralize the pH and precipitate dissolved metals. Following neutralization with lime, the wastewater flowed into a large clarifier outside. Precipitated solids settled to the bottom and was pumped to a sludge holding tank. From June 1986 until operations ceased the sludge was dewatered using a filter press. Sludge cake generated by the filter press was collected in a roll-off container for offsite disposal. Extracted water was recycled back to the clarifier. Prior to the use of the filter press, sludge was dewatered using vacuum pan filters and the filter cake was temporarily stored in an enclosure building prior to offsite disposal. Clarified water was then discharged to the City of Frankfort sanitary sewer system in accordance with a discharge permit. A schematic drawing of the WWTP dated from 1984 is provided in Appendix B.

Lead vapors were generated from molten lead handled in melting pots and casting machines. Plastic fumes were also generated from the battery case heat sealing process. Air handling equipment was used to vent these emissions to baghouses on the southeast side of the building. Lead oxide dust also was vented through ducting to a baghouse (SWMU-2). In general, air from the Facility was cycled through a filtering system called the OSI in the filter building (SWMU-6).

Battery manufacturing operations ceased in 1997. The Site was used by Exide for equipment storage until the demolition project in October 2012. The Site is currently vacant.

3.2.3 Facility Decontamination and Demolition

In October 2012, Exide voluntary performed a decontamination of the facility followed by demolition of the above grade structures. The decontamination and demolition project was completed in January 2013. The scope of work included:

- interior pressure washing and vacuuming to remove dust;

- removal of universal wastes (mercury bulbs and switches, PCB ballasts, miscellaneous chemicals, paints, and petroleum products, etc.);
- dust suppression and air monitoring program;
- demolition of above grade structures;
- cleaning of pits, sumps, and pipes to remove sediment;
- abandonment of piping/drains;
- sampling and sorting of debris for disposal, recycling, or reuse;
- crushing and onsite placement of approximately 3,300 CY of concrete rubble;
- final washing of remaining impervious surfaces;
- collection and onsite treatment of impacted wash water and other contact water;
- demolition of select areas of corroded concrete floor and placement of impermeable cover; and,
- Installation of chain link fence as needed to secure the perimeter.

As part of the demolition work all utility supplies to the Site have been previously cut-off abandoned.

- Potable water – October 22, 2012;
- Electrical Service – September 25, 2012;
- Natural Gas – October 16, 2012; and,
- Sanitary Sewer – January 16, 2013.

3.3 EMPLOYEE HISTORY

As part of the Current Conditions Report development, Dale Reynolds was interviewed. Mr. Reynolds has been an Exide employee since July 7, 1980. Mr. Reynolds currently lives in Frankfort and was the Facility Manager from 1998 through 2017. Additional positions held by Mr. Reynolds include: Material Control Manager, Quality Control Manager, Quality Control Engineer, Lab Technician, Leadman Quality Control Floor Auditor. Following closure of the

facility, Mr. Reynolds has continued to function as the Site caretaker. Mr. Reynolds was involved with the demolition and investigation work that occurred following the closure of the Facility.

Prior to the interview a map (Figure 2 and 4) of the facility showing the SWMUs and AOCs superimposed over the former and current facility layout was provided to Mr. Reynolds along with the following questions:

- *Please confirm your dates of employment with Exide and at the Frankfort Facility;*
- *Please describe your level of knowledge of the Site and former Facility operations;*
- *Do you have any knowledge of use at the three grassy areas/parcels located outside of the current perimeter fence?*
- *In addition to the nine SWMUs and three AOCs identified on the facility plan, are you aware of any other locations where potential contamination pathways are present? This could include leaking sumps, pits, severely damaged flooring, past spills, tanks, waste storage areas, etc.;*
- *Are you aware of any locations where lead, acid, battery casings, or other waste materials were spilled, dumped, buried onsite?;*
- *For areas of the facility "yard" that are currently paved, are you aware of any sites of spills or materials handling that may have occurred on the ground prior to paving?;*
- *Is there currently any problem with trespassers or other members of the general public entering the Site property (albeit without authorization);*
- *Are you aware of any current or former gasoline filling stations in the immediate vicinity of the Site and/or across the street from the property at 1403 Washington Avenue? If so, please describe the approximate location;*
- *During the removal of UST-2 do you recall observing any remnants of an additional UST on the north side of the removal area;*
- *Are you aware of any usage of chlorinated solvents onsite? This includes compounds such as tetrachloroethylene, commonly referred to as PCE; and trichloroethylene, commonly referred to as TCE. Both are also described as "dry*

cleaning fluid" and both are most often used industrially as degreasing compounds. If you are aware of the use of chlorinated solvents onsite. How were they managed as a waste?;

- *Please confirm the date/year when the new formation building was constructed. Was the underlying area paved prior to construction of the building?;*
- *Can you describe the capacity and materials of construction of the former sludge holding tank (SWMU-2); and,*
- *To your knowledge were there ever any wells operated onsite for water production?*

Mr. Reynolds responded in writing and a brief phone call was performed to ensure an accurate understanding of the responses. A complete written summary of the interview is provided as Appendix C.

4.0 ENVIRONMENTAL SETTING

4.1 LOCATION AND LAND USE

The Site is located as shown on Figure 1 (based on USGS Topographic maps for *Michigantown Quadrangle and Frankfort Quadrangle, Indiana-Clinton County 7.5 minute series*). The Site is bounded by North Hoke Avenue to the west, Kelley Avenue to the east, Washington Street to the north, and Norfolk Southern railroad tracks to the south. The Site is located in central Indiana within Clinton County, approximately 50 miles northwest of Indianapolis.

The Site consists of eighteen (18) contiguous/adjacent parcels owned by Exide which encompass approximately 13.7 acres. All but three of the parcels are located within a perimeter security fence. The majority of the area within the fence perimeter is paved (12.1 acres). The three parcels outside the fence are open grassy lots.

During operations approximately 4.5 acres of the Site were under roof and dedicated to battery manufacturing and other directly related operations (wastewater, emission control, offices, etc.). The remaining 7.6 acres of paved area inside the fence was utilized for parking of automobiles, trucks, and trailers. The Site is currently vacant.

Based on a review of historic aerial photos (Appendix A), the three (3) grassy parcels outside of the perimeter fence do not appear to have been used for any operational purpose by Exide. Historic facility plans dated 1984 (Appendix B) indicate that an alley was present to the immediate north of the facility perimeter fence.

4.2 SURROUNDING LAND USE

Residential properties lie across the street from the Site on Hoke and Kelly Avenue; as well as on the opposite side of the railroad tracks to the south. Washington Avenue is immediately north of the Site and has several light industrial commercial properties located in proximity to the Site. No Sanborn maps were available for the Site (see certification in Appendix A).

A review of surrounding properties generated by EDR (Appendix A) has identified various commercial/industrial properties and underground storage tanks located near the Site. This includes the following:

- Wampler Services Inc, 1270 Washington Avenue – this property is located immediately across Washington Avenue from the Site includes an active scrap yard that appears to have been in operation since the late 1960s based on aerial photos. Michael Construction shares the same address and at one time had a storage tank onsite.
- Indiana Gas Company, 500 Hoke Avenue – this property located on the opposite side of Hoke Avenue previously housed storage tanks. This location was also identified as the site of a voluntary cleanup (VRP Number 6980709).
- Norfolk Southern Railroad, 1601 West Ohio Street – this property is located approximately 700 feet south of the Site and a review of available records indicated that there was a leaking UST present at this location. Based on a review of aerial photographs it is unclear whether this is the correct physical address for a UST facility. This location was also identified as the site of a voluntary cleanup (VRP Number 6020104).
- Jay's Car Care, 358 Hoke Avenue – this property is located approximately 700 feet south of the Site.
- An October 6, 1997 letter from Exide's Legal Council (Mr. Lawrence Vanore) to IDEM indicated that in April 1987 a gasoline filling station was present "right across the street from the complainant's house" located at 1403 Washington Avenue. This would place the potential location within 400 feet of the Site.

4.3 TOPOGRAPHY AND SURFACE DRAINAGE

A survey of the Site does not exist. The Site appears relatively flat with a typical ground surface elevation of approximately 850 feet MSL. However, a review of topographic maps for the area around the Site indicates that elevations are generally higher south of the Site and lower north of the Site. It has been observed that stormwater from the eastern half of the Site drains east and

north to Kelley Avenue. Stormwater from the western half of the Site drains west and north to Hoke Avenue. Northern portions of the Site drain north to Washington Avenue.

Stormwater inlets are shown on Figure 3. Water which enters these inlets drains to stormwater pipes on Kelley Avenue or Michigantown Road.

4.4 CLIMATE

Central Indiana has a humid continental climate with cold winters and hot, wet summers. Measureable snowfall usually begins in late November and ends in late March. Daytime temperatures in January, the coldest month of the year, average in the low-mid 30s; with overnight lows in the upper teens. In the summer, daytime highs average in the low to mid 80s; with overnight lows in the mid-60s. Extended periods of higher temperatures are rare due to disruption from cooler and drier Canadian air. The clashing of hot and cold air masses can lead to severe weather, particularly in the spring. Spring is typically the wettest time of the year and is the peak time for tornados. May is typically the wettest month with average rainfall between four and five inches across the State. Average annual precipitation in Clinton County is approximately 39 inches.

4.5 SURFACE WATER HYDROLOGY

Precipitation in the vicinity of the Site can fall as rain in the warmer months or snow during the winter. Most precipitation around the site is managed by a system of paved roads and curbing which direct stormwater into inlets and drainage structures.

An unnamed tributary of the Prairie Creek lies approximately 300 feet north of the Site; on the opposite side of Kelley Avenue. The unnamed tributary eventually drains to the Prairie Creek approximately 1.5 miles downstream of the Site. The Prairie Creek eventually drains into the South Fork of the Wildcat Creek and ultimately to the Wabash River. Most of Indiana (approximately 24,000 square miles) is drained by the Wabash River system. The Site is located in the Upper Wabash River Basin.

A printed FEMA FIRM map for the Site and surrounding vicinity was not available. Panel 18023C0165C was viewed using the FEMA ArcGIS viewer and indicated that the panel containing the Site is an "Area of Minimal Flood Hazard".

4.6 GEOLOGY

As the Laurentide ice sheet began to retreat from present day Northern Indiana and Northwest Ohio between 14,000 and 15,000 years ago, it receded into three distinct lobes. The eastern or Erie Lobe sat atop and behind the Fort Wayne Moraine. Meltwater from the glacier fed into two ice-marginal streams, which became the St. Joseph and St. Marys Rivers. Their combined discharge was probably the primary source of water for the proglacial Wabash River system. Rich prairie soils extend over central Indiana. Some clays in east-central Indiana are compact with poor drainage and frequent ponding of water. Till (material deposited directly by glaciers) forms flat to hummocky plains that dominate the central portion of the state. The thickness of the glacial deposits ranges from 100 to 400 feet throughout Clinton County.

The Site and surrounding region is immediately underlain by Fincastle-Crosby soils (see *EDR* soil report provided in Appendix A). This is a silty loam with slow infiltration rates (Class C) and is somewhat poorly drained. The area is characterized by swell and swale topography. Fincastle soils are typically observed on rises and have a brown silt loam surface layer, and yellowish brown, mottled silty clay loam to clay loam subsoil. Crosby soils are found on high rises and have a brown silt loam surface layer, and yellowish brown, mottled silty clay loam, clay loam, and loam subsoil.

Fill materials are generally present in the upper 18 – 24 inches of the onsite soil strata. Borings performed as part of the Hazardous Waste Pile Closure (1998 – 2000) identified fill materials in depths of up to 5 feet below ground surface in the northern portion of the Site. During the 2014 soil investigation, shallow geoprobe borings (4 feet to 8 feet in depth see Appendix D) identified silty clay soils in a majority of borings. Sandy fill materials were identified in borings performed near the rail road embankment on the south portion of the Site, beneath Old Formation, and beneath the former WWTP. All of these locations were described as likely to have had grading or fill placement performed.

Debris (brick/masonry fragments, piping, wire) was observed in the UST-2 removal excavation performed in 2014, but was not observed in geoprobe borings elsewhere onsite. The deepest boring performed onsite during the Initial Site Characterization (ISC) investigation reached a depth of sixteen (16) feet below ground surface. Bedrock was not encountered.

The Site appears to fall near the divide between Devonian and Silurian bedrock units. Devonian formations typically have a carbonaceous shale on the upper portion and are underlain by limestone, dolostone and shale. Silurian bedrock contains the latter rock types. Indiana bedrock geology features a broad anticline with a slight plunge to the northwest. Due to the broadness of the anticline it is often referred to as an arch. Bedrock beneath the Site is located at approximately 550 feet MSL (approximately 300 feet bgs).

4.7 HYDROGEOLOGY

The Tipton Complex Aquifer System is characterized by unconsolidated deposits that are quite variable in materials and thickness. Aquifers within the system range from thin to thick and include single or multiple intratill sands and gravels. The aquifers are highly variable in depth and lateral extent and are typically confined by thick clay layers. The total unconsolidated thickness of the Tipton Complex Aquifer System generally ranges from about 200 feet to over 400 feet in Clinton County. The potentiometric surface of the regional unconsolidated aquifer is approximately 800 feet MSL (approximately 50 feet bgs).

This system is capable of meeting the needs of domestic and most high-capacity users in the county. Aquifer layers utilized in the Tipton Complex Aquifer System are generally 5 to 10 feet thick sands and/or gravels. These sands and gravels are overlain by a till cap which is commonly 65 to 190 feet thick with thin intratill sand and gravel layers. Wells in this system are typically completed at depths ranging from 68 to 195 feet. Domestic well yields are commonly 15 to 65 gpm and static water levels are generally 15 to 35 feet below the surface. There are 8 registered significant ground-water withdrawal facilities (29 wells) in this system in Clinton County. High-capacity well yields of up to 1,200 gpm are reported.

The Tipton Complex Aquifer System is generally not susceptible to contamination because it is typically overlain by thick clay deposits. However, in places surficial clay thickness is thin or not present. These are at moderate to high risk to contamination by surface sources.

4.8 GROUNDWATER MONITORING AND USE

Only limited groundwater monitoring has been performed on the site. It is unknown whether the groundwater was ever used to supply facility water needs during earlier periods. However, for at least the latter part of the operational history (1980 and later) the Facility was only supplied with potable water from multiple City of Frankfort municipal supply lines and no groundwater usage is noted by Mr. Reynolds. The municipal water supply lines were cut and capped in October 22, 2012.

During the 2014 UST removal, depth to groundwater measurements were inconclusive. The depth to water measurements observed in temporary geoprobe well borings on July 1, 2014 was approximately 11-12 feet below ground surface. However later on that same day groundwater was observed at depths as shallow as approximately 3 feet bgs. In addition, heavy rainfall occurred during the UST removal period. During excavation of the USTs groundwater was typically observed at a depth of approximately 6 feet. This may be indicative of perched water conditions above shallow clay lenses as well as stormwater infiltration/run-on. A summary of groundwater elevations observed during the UST removal is provided on Table 2.

The hydraulic gradient observed in the borings performed as part of the UST removal appears to mimic the site topography and flows in a north-northeast direction corresponding to lower surface elevations. An intermittently flowing creek is located approximately 300 feet north of the UST removal groundwater measurement locations.

In 2014, during the UST removal a review of the Indiana Department of Natural Resources – Division of Water Well Record Database was performed. The review indicated that there are eighty-five (85) high capacity (greater than 70 gallons per minute) and municipal water supply wells within a 2-mile radius of the Site. In addition, there are thirty-three (33) wells with a capacity

of less than 70 gallons per minute located within a one (1) mile radius of the Site. IDEM provided a determination on May 12, 2014 that the Site is not located within a wellhead protection area (WHPA). The closest private well appears to be approximately 1,000 feet east of the Site. Residences in the immediate vicinity of the Site are supplied with municipal water. Copies of individual well construction records and a map with the location is provided in Appendix E.

5.0 REGULATORY HISTORY

5.1 RCRA/ENVIRONMENTAL PERMITS

On August 18, 1980, General Battery submitted a Notification of Hazardous Waste Activity for hazardous waste generation; and treatment, storage, and disposal of hazardous wastewater and associated sludge. On November 19, 1980, General Battery filed a Part A Hazardous waste permit application for the on-site wastewater treatment facility and for storage of waste water treatment sludge in an enclosed building. On October 18, 1982, the facility requested that the wastewater treatment unit be withdrawn from the Part A application, because the RCRA amendments no longer required a RCRA permit for such units. On December 8, 1982, EPA approved the withdrawal of the waste water treatment unit form the Part A application.

On September 30, 1983, the Indiana State Board of Health (ISBH) conducted a RCRA Generator Compliance Inspection at the facility. Based on this inspection, the facility was issued a Notice of Violation (NOV) on October 31, 1983, for lack of personnel training records. In addition, copies of the contingency plan had not been submitted to the state and local emergency organizations.

On August 2, 1984, ISBH conducted another RCRA Generator Compliance Inspection at the facility. On October 22, 1984, the facility was issued NOV V-008 for not providing documentation to confirm compliance with 40 CFR 265, Subpart L for storage of D008 hazardous waste sludge in a waste pile, and insufficient documentation to show full compliance with personnel training requirements. In January 1985, the facility submitted the missing information to ISHB, as well as a closure plan for the waste pile. On September 9, 1985, ISBH issued NOV V-197 to General Battery for incomplete financial assurance documentation related to closure of the waste pile. On September 17, 1985, the facility submitted a revised closure plan to address ISBH's comments on the draft dated April 1, 1985. On September 23, 1985, the facility submitted additional financial assurance documentation in response to the September 1985 NOV. On October 8, 1985, ISBH issued a notice of compliance for the two NOVs (V-008 and V-197). ISHB approved the waste pile closure plan on October 22, 1985, and approved the certification of completion of total closure of the waste pile on November 10, 1986.

On January 7, 1985, General Battery submitted a closure plan for an indoor waste pile that was being used for management of wastewater treatment sludge. This action was taken in order to comply with EPA and Indiana hazardous waste regulations for owners/operators of hazardous waste TSD facilities. The closure plan was revised and resubmitted on September 17, 1985. On October 22, 1985, the ISBH approved the closure plan. General Battery implemented the closure in June 1986. Clean closure certification of the waste pile was approved by IDEM in November 1986. Following closure of the indoor waste pile, wastewater treatment sludge was accumulated in roll-off containers for less than 90 days prior to offsite disposal.

On February 19, 1987, General Battery requested that IDEM withdraw the RCRA Part A permit application in its entirety because the waste pile at the facility had been clean closed with IDEM approval. On April 29, 1987, IDEM determined that the facility qualified as a generator only and approved withdrawal of the permit application. On August 24, 1988, the facility revised their Notification of Hazardous Waste Activity to reflect generation of waste naphtha. Based on waste generation rates at that time, the facility was classified as a large quantity generator of RCRA hazardous waste.

On January 27, 1987, IDEM conducted another RCRA compliance inspection at the facility. On April 29, 1987, IDEM issued NOV V-492 which cited the following violations: personnel training records were inadequate, personnel had not completed an annual review of initial training, the contingency plan was incomplete, the start of the 90-day generator accumulation period was not labeled on the drums in the drummed waste accumulation area, and the hazardous waste containers were not inspected weekly for leaks and deterioration. In response to facility information submitted on June 5, 1987, IDEM issued a Notice of lnadequacy on August 19, 1987. General Battery provided additional information to IDEM on September 10, 1987, and IDEM issued a Notice of Compliance for NOV V-492 on October 9, 1987.

Following completion of the Hazardous Waste Pile remediation in November 2000, Exide submitted the Hazardous Waste Pile Closure Report to IDEM on January 9, 2001. IDEM approved the closure report on February 14, 2001. With closure of this unit, the facility was reclassified as a RCRA generator.

In March 1988, IDEM conducted a Preliminary Review Visual Site Assessment (PR/VSI) at the site. The PR/VSI identified five solid waste management units (SWMUs) which are discussed in Section 3.6. The PR/VSI recommended that soil samples be collected from several depths beneath all baghouses as well as the vicinity of the filter house and analyzed for lead.

On January 31, 1997, IDEM conducted a complaint investigation at the facility. The complaint was made by an anonymous person who identified himself as a former employee of Exide. The complaint alleged that two tractor trailers full of scrap batteries with acid were dumped in a 30-foot deep pit in1991. The pit was allegedly located in a paved parking area on the north side of the plant between the weigh scales and the truck monitor office. Based on the results of the investigation, there was no evidence found to support the allegations that scrap batteries had been dumped and buried. The IDEM inspector recommended that no further action was necessary.

On June 17, 1997, IDEM conducted a RCRA Compliance Evaluation Inspection (CEI) at the facility. As a result of the inspection, the facility was issued a NOV on August 18, 1997. In the NOV, the facility was cited for five violations: creation of an unpermitted 30-foot by 30-foot waste pile in the northeast comer of the facility; failure to meet the general requirements for a waste pile, such as run-on/run-off management, wind dispersal controls, and a leachate collection system; the facility contingency plan did not properly identify the addresses of all emergency coordinators; one pallet of spent D008 filters was improperly labeled; and one pallet of spent D008 filters was improperly containerized during accumulation. The IDEM inspector identified the material in the waste pile as being hazardous lead-contaminated soils carrying the D008 waste code that were generated during cleanup following a fire at the facility. However, according to the Hazardous Waste Pile Closure Plan, the materials in the waste pile were lead contaminated soils excavated during the course of a remodeling project at the Exide facility in 1996.

IDEM conducted another RCRA CEI at the facility on June 22, 2001. This inspection revealed that the facility was being used as a storage warehouse for equipment from Exide's other plants. At the time of the inspection, the facility was classified as a small quantity generator of D008 hazardous waste. These wastes included floor sweepings and debris associated with ongoing cleanup of the former manufacturing building. No violations were observed during the CEI.

In December 2001, a previous employee of Exide sent a complaint to the Ohio governor's office which was then forwarded to IDEM. The registered complaint alleged that the facility had excavated holes in the ground in two areas, filled the holes with scrap batteries, and covered the holes with concrete. The first area was allegedly located under the concrete inside the "old battery charging area." The second area was allegedly located near the loading dock on the east side of the contaminated gravel pile on the north side of the facility near the wastewater treatment plant. On January 14, 2002, IDEM initiated another complaint investigation of Exide to address these allegations. On April 16, 2002, IDEM conducted a citizen compliant inspection (CCI) at the facility, meeting with a long time employee of Exide, who denied the allegations and indicated that the batteries were recycled and managed as a valuable commodity. IDEM representatives inspected the alleged areas of concern and concluded that there was no basis to justify the allegations. The CCI Summary letter sent to Exide on May 14, 2002, indicated that no violations were observed.

IDEM conducted another RCRA CEI of the Exide plant on June 21, 2010. The inspection report noted that no hazardous waste was generated at the facility in 2009, and only one shipment of floor sweepings (D008) had occurred in 2010 as of the time of the inspection. No violations were observed during the inspection.

An operating permit (#16313) was issued by IDEM on June 30, 1983 which regulated lead emissions from the facility during operations. During the demolition project in October 2013, IDEM Office of Air Quality performed an inspection of the Site and did not note any deficiencies or violations.

With the exception of the recommendation to sample around the filter house and baghouses from the March 1988 PR/VSI; none of these previous inspections appear to have findings which presently require a follow-up action.

5.2 CITY OF FRANKFORT PERMITS

During manufacturing operations and prior to demolition, the WWTP discharged effluent from the onsite WWTP to the sanitary sewer in accordance with a permit obtained from the City of Frankfort. During the 2012 demolition project the City of Frankfort issued permits for fencing, demolition, and water discharge. Inspections were also performed by the Building Inspector and the Water Treatment Plant Superintendent. In 2014, accumulated waters within the UST removal excavations was tested and discharged to the Frankfort Sanitary Sewer under a temporary authorization.

5.3 SPILL, DISCHARGE, AND CLEANUP HISTORY

5.3.1 1976 Acid Spill

On September 8, 1976, valve malfunction on an acid mix tank resulted in approximately 500 gallons of sulfuric acid being spilled on the ground. The sulfuric acid flowed into a sanitary sewer and was discharged to the unnamed tributary of Prairie Creek northeast of the Site. Approximately 1,800 pounds of hydrated lime was applied to the Creek at a distance of approximately 0.75 miles downstream of the Spill. The pH of Prairie Creek downstream of the tributary confluent was measured to be 7.5. No fish kill was observed in the tributary or the Creek.

This incident does not appear to require any specific follow-up action.

5.3.2 1986 – 1988 Soil Cleanup

On April 3, 1986, IDEM conducted a RCRA compliance inspection at the facility and identified two areas of potential soil contamination. On July 18, 1986, IDEM issued NOV V-137 to the facility for improper labeling and closure of hazardous waste containers, deposition of oil contaminated boiler blow-down water on the ground next to the castings/grid building, and releases of wastes from spent batteries on the ground in the battery loading area. The NOV requested that the facility submit a cleanup plan for removal and disposal of contaminated soil in

the casting building and battery loading area. On December 15, 1986, IDEM issued a Notice of Inadequacy regarding plans the facility submitted for cleanup of the casting building and battery loading area. In this Notice, IDEM requested that soil excavated next to the casting building be tested for polychlorinated biphenyls (PCBs) and total halides, and that the proposed disposal site for the excavated soil be identified. In addition, IDEM requested that analytical results for the contaminated soil in the battery loading area be submitted. On March 27, 1987, IDEM issued another Notice of Inadequacy regarding NOV V-137 requesting the following: analytical results for excavated soil, General Battery's rationale for a 2-foot depth of excavation in the area of the grid cast building, analyses of the excavated soil from both the grid casting building area and the battery loading area for total lead and total cadmium, and excavation of all contaminated soil above background levels. The Notice also requested submission of a sampling and analysis plan for the castings/grid building and battery loading areas, rationale for sample locations chosen, and background metals concentrations.

On May 29, 1987, the facility reported that a plant engineer collected a soil sample in the stained area near the casting building, excavated soil to a depth of approximately 2 feet where the soil was visibly clean, and took another sample. The samples were analyzed for lead, cadmium, oil, and grease. Following receipt of the December 1986 Notice of Inadequacy letter, Exide collected additional samples of the excavated soil and soil in place at the bottom of the 2-foot excavation; these samples were analyzed for PCBs and total halides. In addition, the facility indicated that they would collect samples in a grid pattern at the battery loading area, with one sample collected every 10 feet. The facility also proposed to collect background samples at a depth of 5 feet bgs at random locations around the site. Exide submitted the results of the soil sampling at the loading dock on August 11, 1988 (summarized in Section 6.2). Based on the results from the grid sampling effort that indicated significant lead contamination in soil, Exide proposed to excavate an area of 35 feet by 45 feet to a depth of 0.5 feet bgs. Soil samples would then be collected from the bottom of the excavation to ensure that a cleanup level of 2,000 mg/kg for lead was attained.

On September 15, 1988, IDEM issued a Letter of Inadequacy indicating that the proposed cleanup level of 2,000 mg/kg for lead was unacceptable. This letter also required Exide to collect a minimum of three samples at least 100 feet from any roadway or process area to establish

background levels of total lead. The cleanup standard would be set at the mean range of the background sample results. On July 17, 1989, IDEM sent Exide a letter indicating that the acceptable cleanup level for lead in soil was 78 mg/kg, based on background sampling. On July 18, 1989, IDEM and Exide agreed that Exide would excavate 1 foot of soil from the surface of the 35 foot by 45 foot spill area and apply a lime buffer to the bottom of the excavation before backfilling to control pH. The soil removal was implemented as planned and IDEM issued a Notice of Compliance for V-327 on August 4, 1992.

No additional follow-up action appears to be required for this item.

5.3.3 1987 Alleged UST Release

On March 2, 1987, IDEM's Emergency Response Branch (ERB) filed an Incident Report for Incident #873001. This report was a follow-up to a citizen complaint that alleged that fuel oil had been detected in a residential basement and two storm sewer manholes in close proximity (within 50-ft of 20,000 gallon oil tank) to the General Battery facility. ERB collected and analyzed a sample of the material for oil and grease. Sampling results indicate that the material was 83.9% oil (by weight) in one manhole and only 0.92% oil (by weight) in another. As a result of this incident, ERB requested that the facility perform tightness testing on its underground storage tanks (USTs), particularly the 20,000-gallon fuel oil UST located on the north side of the property and approximately 50 feet from an affected manhole. On March 4, 1987, General Battery conducted tightness testing on three USTs, including the 20,000-gallon #2 fuel oil tank, a 10,000-gallon fuel oil tank on the southeast side of the property, and a 10,000-gallon fuel oil tank on the southwest side of the property. It is noted that the location descriptions for these tanks are relative. The 10,000 gallon fuel oil tank was located centrally on the property, but south of the Old Formation area. The 10,000 gallon fuel oil tank on the southeast side of the property was located beneath the former Fuel Shed location to the east of the Send Out area in the northeast corner of the Site and some records indicate it was used for storage of diesel fuel.

All three tanks failed to meet the tightness testing criteria. In April 1987, the facility closed the 20,000-gallon fuel oil tank in place. No evidence of release was reportedly observed at the time of the tank closure. The diesel UST was permanently taken out of service in December 1991. No information regarding the status of the 10,000-gallon fuel oil tank was available to ascertain the condition or usage after 1991.

On April 15, 1987, IDEM requested that the facility complete a narrative spill report for the fuel oil release identified in the storm sewer on March 2, 1987. At that time, IDEM did not require an Initial Site Characterization (ISC) because heating oil tanks were not regulated under IDEM's Leaking UST (LUST) program. On April 30, 1987, the facility submitted a spill response report to IDEM indicating that they were unaware of any spill occurring on their property. In September 1997, IDEM's LUST Section requested that the facility complete an ISC for Incident #8703001, because the initial incident report indicated that the release was from a diesel UST. In a letter from Exide's legal counsel (Mr. Lawrence Vanore) to the IDEM LUST Section in October 1997, Exide indicated that the former #2 fuel oil UST on their property was not believed to be the source of the release related to Incident #873001, because no releases were observed during closure of the tank. IDEM's LUST Section referred Exide's response to the Emergency Response Section, who handles releases from non-RCRA-regulated USTs. Currently, LUST incident #8703001 is listed as discontinued but still active.

The citizen complaint was filed by a resident at the 1403 Washington Avenue (a.k.a. Michigantown Road) property which is located approximately 150 north of the perimeter fence and is separated from the perimeter of any manufacturing related operations by the grassy lots owned by Exide as well as another residential property. The letter from Mr. Vanore to IDEM also indicated that in April 1987 a gasoline filling station was present "right across the street from the complainant's house". A more accurate location/description of the referenced gasoline station could not been obtained from the files, although a review of Google Earth aerials since 1999 and the earlier aerials obtained during preparation of this Current Conditions Report did not confirm or refute the statements by Mr. Vanore.

5.3.4 1996 Hazardous Waste Pile Removal

In February 1996, Exide removed hazardous wastes managed in a 30-foot by 30-foot waste pile and disposed of them at a RCRA-permitted off-site TSD facility. An additional 6 inches of soil underlying the waste pile were removed during this action. Clean Harbors conducted the sampling, characterization, and removal of hazardous waste and underlying soil. According to the facility, there were no indications of spillage or run-off outside the immediate waste pile area.

5.3.5 2000 Hazardous Waste Pile Closure

In August 1997, Exide and IDEM initiated negotiations to resolve the issues arising from the June 1997 inspection (Section 5.1), and Exide submitted additional information regarding the waste pile to IDEM on September 1997. On July 1998, Exide entered into an Administrative Order (AO) with IDEM that required Exide to determine the concentration of lead in soils beneath the former waste pile. In August 1988, soil samples were collected from four soil borings advanced within the former waste pile footprint and analyzed for total lead. The soil samples were collected every 6 inches to a depth of 3 feet bgs, and then at 4 feet bgs and at 5 feet bgs, for a total of 24 samples. Total lead concentrations decreased with depth before increasing near the 5-foot depth interval.

On September 18, 1998, Exide submitted the sampling results for the former waste pile to IDEM. Following review of this documentation, IDEM directed Exide to submit a RCRA Closure Plan to complete the requirements of the AO. On March 30, 1999, Exide submitted the Hazardous Waste Pile Closure Plan to IDEM. On March 28, 2000, IDEM approved the March 30, 1999 closure plan, with revisions dated September 9, 1999 (Addendum No. 1), January 20, 2000 (Addendum No. 2), and March 8, 2000 (Addendum No. 3). Exide conducted sampling and closure activities at the facility in accordance with Hazardous Waste Pile Closure Plan and Addenda Nos. 1, 2, and 3.

On March 22, 2000, in accordance with Addendum No. 3 to the closure plan, Exide conducted soil sampling to establish background lead concentrations for shallow fill in the vicinity of the former waste pile. Six soil samples were collected of fill materials to a maximum depth of 18 inches bgs.

Total lead concentrations in these samples ranged from 165 mg/kg to 2,970 mg/kg. As approved by IDEM in a letter dated June 29, 2000, Exide removed a uniform layer of 18 inches of soil in the proposed 30-foot by 30-foot excavation area in November 2000. No confirmatory samples were collected at the bottom of the excavation because previous sampling events in the proposed excavation area indicated that lead levels below 18 inches bgs were below the Risk Integrated System of Closure (RISC) Tier 1 Residential values (400 mg/kg).

Fate and transport analysis (SOLUTE model) was performed by Advanced GeoServices during the development of the closure plan Addenda. The model assumptions were very conservative (over-estimation of lead mobility). The model results indicated that dissolved lead migration from the waste piles was not able to have a discernable impact on groundwater or deeper soil. Lead impacts observed in deeper soils around the waste pile area were likely due to the presence of various fill materials observed at depths of up to 5 feet bgs.

On November 8, 2000, the excavation was backfilled with clean soil imported from Paddock Brothers, Inc. of Frankfort, Indiana. The excavated soils were characterized as hazardous for lead prior to excavation and disposal. Approximately 246 tons of excavated soil were treated to non-hazardous Toxicity Characteristic Leaching Procedure (TCLP) levels of lead and disposed at Max Environmental Inc.'s Mill Services TSD facility in Yukon, Pennsylvania. Exide submitted the Hazardous Waste Pile Closure Report to IDEM on January 9, 2001. IDEM approved the closure report on February 14, 2001. A copy of the Hazardous Waste Pile Closure Report is provided as Appendix F.

5.3.6 2014 UST Closure

During the 2012 facility decommissioning project, USEPA visited the Site and inquired about the status of three USTs believed to be located onsite. Exide subsequently performed a Site reconnaissance and a review of internal records. It was determined that up to three USTs existed onsite (see Section 5.3.3) although the descriptions of the contents and locations varied somewhat between different documents.

- 10,000 gallon heating oil UST (unregulated) that was not closed; this UST is identified as UST-1 in closure documents submitted to IDEM in 2014 and herein.
- 10,000 gallon diesel fuel UST that was taken out of service in 1991 but not closed. This UST is identified as UST-2 in closure documents submitted to IDEM in 2014 and herein.
- 20,000 gallon #2 fuel oil UST that was closed in place in 1988 (referred to as UST-3 herein).

Although, not known at the time of removal the location of UST-3 appears to be adjacent to UST-2 near the former Fuel Shed area in the northeast portion of the Site (east of Send Out). UST-1 was located in the central portion of the Site (south of Old Formation). UST-1 and UST-2 were removed on April 16, 2014. The tanks appeared to be intact at the time of the removal. No damage, holes, or penetrations were observed prior to removal. No free product was observed during the removal. However, hydrocarbon odors and soil discoloration were observed in soils surrounding the tanks. The suspected releases were reported to IDEM LUST section on April 17, 2014. LUST #201404509 was assigned to the UST-1 release and LUST #201404505 was assigned to the UST-2 release.

Soils immediately around the tanks consisted of a non-native sand backfill. Native silty clay soils were observed further away from the tank. Real time soil screening with a photo-ionization detector (PID) was performed during the excavation and post-excavation confirmation samples were collected from the bottoms and sidewalls of the excavations. Analysis for poly-cyclic aromatic hydrocarbons (PAHs), semi-volatile organic compounds (SVOCs), and volatile organic compounds (VOCs) was performed. On May 5-8, 2014 additional soil excavation and post-excavation sampling was performed. Approximately 1,092 tons of impacted soils (as determined by direct observation, PID screening, and/or laboratory data) were removed and disposed of as part of the UST-1 and UST-2 removal. On July 28–August 1, 2014 the excavations were dewatered and backfilled.

5.3.6.1 **UST-1**

The final post-excavation soil samples indicated no exceedances of the 2014 IDEM RISC residential direct contact screening limits of migration to groundwater screening limits. Water collected within the excavation on April 16, 2014 had exceedances of the 2014 IDEM RISC residential tap water screening limits for "naptha compounds" such as: naphthalene, 1-methylnaphthalene, 2-methylnaphthalene, acenaphthene, benzo(a)anthracene, benzo(b)fluoranthene, and fluorine. However, a sample of excavation water in July did not have any such exceedances (likely due to source removal).

Based on the soil and water data presented during the UST removal, IDEM required that a limited subsurface investigation (LSI) be performed consisting of three groundwater samples collected within twenty feet of the UST-1 excavation. No exceedances of 2014 IDEM RISC screening limits for residential tap water or vapor exposure were detected. A copy of the Limited Subsurface Investigation report is provided as Appendix G.

5.3.6.2 **UST-2**

The final post-excavation soil samples indicated no exceedances of the 2014 IDEM RISC residential direct contact screening limits. However four soil samples collected from sidewalls and offset trenches detected exceedances of the migration to groundwater (MTG) standard for naphthalene. One soil sidewall sample also indicated an exceedance of the MTG standard for 1-methylnaphthalene. IDEM required that an initial Site Characterization be performed. Samples of water collected from within the UST-2 excavation on April 16, 2014 and May 7, 2014 indicated exceedances of the 2014 IDEM RISC residential tap water screening limits for naphthalene and vinyl chloride. The excavation water sample collected on May 7, 2014 also detected exceedances for cis-1,2-DCE, trans-1,2-DEC, and trichloroethene (TCE). The detections of chlorinated solvents were unexpected and not typically attributed to petroleum USTs. These detections were reported to IDEM and an Initial Site Characterization (ISC) was required.

As part of the ISC three (3) additional soil borings and three (3) additional temporary well geoprobe borings were performed within 20 feet of UST-2. Soil sample results continued to note exceedances of the MTG standards for vinyl chloride, cis-1,2-DCE, and/or TCE in deeper intervals (10 – 12 feet depth and/or 15 – 16 feet depth). All three groundwater samples indicated detections of the various chlorinated solvent compounds at concentrations exceeding the 2014 IDEM RISC residential tap water standard. 1,1-DCA, TCE, and vinyl chloride were also detected at concentrations exceeding the screening limits for vapor exposure. A copy of the Initial Site Characterization Report is provided as Appendix H.

5.4 WASTE GENERATION AND MANAGEMENT

5.4.1 During Manufacturing Operations

Because of the long and varied ownership of the Facility, specific information regarding past waste streams is not available. In general, during the operation of the facility, production operations resulted in the generation of wastewater, solids captured by air emission controls, sludge, used containers, off-spec products, and various hazardous and non-hazardous wastes. Secondary waste streams included items such as waste oils, fluids, filters, sorbent materials, personnel protective equipment (PPE), and office wastes.

Baghouse dust was accumulated in waste drums. Used air filters from the filter building as well as used PPE were accumulated onsite. The baghouse dust, filters, floor sweepings and used PPE were characterized as hazardous due to the lead content (D008). These materials were stored in the hazardous waste accumulation area (SWMU-4) prior being sent to a General Battery/Exide lead smelter facility for recycling.

Prior to June 1986, sludge from WWTP operations was accumulated for less than 90 days in an indoor waste pile (SWMU-1). Following closure of the indoor waste pile in June 1986, wastewater sludge (filter cake) was collected in a roll-off container for less than 90 days prior to offsite disposal (landfill).

Waste naphtha from two parts cleaners (SWMU-9) in the basement maintenance area was disposed of by Safety-Kleen.

5.4.2 Post-Shutdown

Since the cessation of manufacturing operations in 1997 the only significant waste generation that has occurred onsite has been associated with various cleanup operations, the decontamination/demolition project, and the UST removal.

Floor sweepings and debris containing lead were generated in 1997-1999, collected in drums, and transported to an Exide lead smelter for processing. In December 1999, Heritage Environmental Services removed and disposed of waste from cleanup operations at the baghouses. One shipment of floor sweepings (D008) was made in 2010.

During closure of the hazardous waste pile in November 2000, approximately 246 tons of excavated soil were treated to achieve non-hazardous levels of TCLP-lead and disposed at the Mill Services TSD facility in Yukon, Pennsylvania.

During the October 2012 – January 2013 decommissioning project the following wastes were generated:

- 16.53 tons of asbestos containing material (ACM) disposal offsite (Clinton County Landfill non-hazardous)
- 508 tons of scrap metal recycled offsite
- 1,073 tons of Construction and Demolition Debris disposed offsite (Clinton County Landfill non-hazardous)
- 1,407 tons of hazardous materials disposed offsite (Heritage Environmental Services hazardous); and,
- collection and onsite treatment of 18,834 gallons of impacted wash water and other contact water prior to discharging to the Frankfort Sanitary Sewer under a discharge permit.

During the 2014 UST removal/closure the following wastes were generated:

- Following cleaning the steel tank bodies were recycled as scrap;
- 1,092 tons of petroleum contaminated soils disposed offsite (Clinton County Landfill non-hazardous);
- 10,200 gallons impacted water was collected during UST removal and disposed offsite (Future Environmental of Indianapolis non-hazardous);
- Up to 80,000 gallons of ground water and stormwater accumulated in the UST excavations while awaiting results of post-excavation sampling (estimated based on excavation dimensions). These waters were tested and discharge to the Frankfort Sanitary Sewer under a temporary authorization;
- 6 drums of petroleum sludge (removed from USTs during cleaning) were generated and disposed of by CGS Services Inc. of Morristown, Indiana (non-hazardous); and,
- 86 tons of concrete/asphalt rubble were disposed offsite.

The Site is currently vacant and no waste is being generated or managed onsite.

5.5 DESCRIPTIONS OF SWMUs AND AOCs

Figure 4 depicts the current site conditions (2017 aerial photo) along with the locations of the SWMUs and AOCs.

5.5.1 SWMU-1 Former Waste Pile #1 (Sludge Storage Area)

The former waste pile, also referred to as the Sludge Storage Area, was located in the sludge storage building on a concrete floor. The sludge storage building footprint was approximately 18 ft. x 18 ft. The waste pile was used for accumulation (less than 90 days) of dewatered calcium sulfate sludge (D008 hazardous waste) from wastewater treatment operations at the facility. Prior to June 1986, the calcium sulfate sludge was dewatered in a vacuum pan filter, and temporarily

accumulated at SWMU 1. Approximately 324 tons of dewatered sludge were generated each year and transported off site for disposal at the Adams Center Landfill in Fort Wayne, Indiana.

At the time of the 1988 PR/VSI, the waste pile no longer existed. The waste pile underwent closure in accordance with an ISBH-approved closure plan in 1986. No history of any releases from this waste pile has been identified because the waste pile was located indoors in an enclosed area on a concrete floor. Leachate generated during the temporary accumulation period was collected and transferred to the wastewater treatment system for processing.

According to the approved closure plan, sludge remaining in the waste pile at the time of closure was placed in a roll-off container and transported to the Adams Center Landfill in Fort Wayne, Indiana. The concrete walls and floors of the sludge storage area and adjacent areas were washed to remove contaminants. The building was subsequently modified to enable sludge to drop directly from dewatering equipment into a large roll-off container. Exide submitted closure certifications to ISBH in June and July 1986. ISBH issued a completion of closure letter to the facility in November 1986.

No additional investigation is necessary for SWMU-1.

5.5.2 SWMU-2 Sludge Storage Tank

The sludge storage tank was located inside the wastewater treatment building on concrete slab and was used in conjunction with wastewater treatment operations at the facility. The sludge storage tank was used for temporary accumulation of liquid calcium sulfate sludge prior to dewatering. Sludge was withdrawn from the wastewater treatment system's clarification tank and pumped to this sludge storage tank for holding prior to dewatering. The sludge was classified as D008 hazardous waste for its lead content. After dewatering, the liquid waste was transferred back to the treatment system's reaction tank; the dewatered sludge was routed to SWMU 1. It is believed that use of the SWMU 2 sludge holding tank ended in 1997, when battery manufacturing operations ceased at the Exide facility.

The sludge storage tank was located inside on concrete slab. The tank measured approximately 12 feet in diameter and 12 feet tall (maximum capacity 10,000 gallons) and was constructed of fiberglass. The tank was in active operation at the time of the PR/VSI in 1988; however, no recommendations were provided for this unit in the PR/VSI report. Spilled material would have been contained by the building. No history of any releases has been identified with the sludge storage tank.

The WWTP facility including the sludge storage tank was decontaminated and demolished/removed as part of the 2012 decommissioning activities. No sludge remained in the sludge storage tank and no evidence of a release was observed at that time.

In 2014, soil boring B-13 was performed in the vicinity of the former WWTP. Refusal was encountered at a depth of 2-feet bgs. However, the 1.5 to 2 feet deep sample interval produced a lead detection of 13,200 mg/kg.

5.5.3 SWMU-3 Baghouses

The baghouses were located outside behind the plant building. When the facility was used to manufacture batteries, lead fumes from molten lead and lead oxide dusts were vented to the baghouses. Dust that accumulated in the baghouses was classified as D008 hazardous waste due to its lead content. The baghouse dust was transferred to drums, accumulated in the hazardous waste accumulation area (SWMU- 4) for less than 90 days and shipped to a lead smelter facility in Pennsylvania for reclamation.

The PR/VSI described the ground beneath the baghouses as appearing dark, indicating possible contamination from lead dust. The VSI recommended that soil samples be collected from several depths beneath all baghouses and analyzed for lead. It is expected that use of the baghouses ended in 1997, when the facility ceased manufacturing batteries.

A CEI conducted by IDEM in June 2001 indicated that cleanup of the baghouses had been completed, and that Heritage Environmental Services had removed and disposed of the waste generated from the cleanup activities. It is not known whether any post-cleanup samples were collected from the area beneath and around the baghouses. The remaining baghouse structures were removed from the Facility as part of the 2012 decommissioning.

In 2014, soil boring B-18 was performed in the vicinity of the former baghouse and filter building. B-18 was advanced to a depth of 8-feet bgs and nine samples were collected from various intervals. The maximum lead detection of 510 mg/kg occurred in the 0.5 – 1 foot depth interval. No other intervals had lead detections which exceeded an IDEM RISC screening level.

5.5.4 SWMU-4 Hazardous Waste Accumulation Area

The hazardous waste accumulation area was located inside the south-central end of the plant building. The area is approximately 15 feet by 20 feet. When the facility was manufacturing batteries, this hazardous waste accumulation area was used for accumulation (less than 90 days) of drums containing lead-contaminated dust (D008 waste) from the baghouses, prior to off-site transport to a secondary lead smelter in Pennsylvania for recycling. Used air filters from the filter building and drums of used gloves, respirators, and floor sweepings were also accumulated in the hazardous waste accumulation area and transported off site as D008 waste to Reading, Pennsylvania for recycling. Approximately 125 tons of lead-containing materials were generated in 1984.

Hazardous waste drums were accumulated on a concrete floor inside the plant building. The used air filters shrink-wrapped with plastic were accumulated on pallets in the hazardous waste accumulation area. There are no documented releases from this unit, but spilled material would likely have been contained by the building. No violations associated with this unit were noted during the June 2001 and June 2010 CEIs. No hazardous waste was being accumulated in the hazardous waste accumulation area at the time of the June 2010 CEI.

No further action is needed for this SWMU.

5.5.5 SWMU-5 Wastewater Treatment Unit and Sump

The wastewater treatment facility was installed in 1970 and was located in the northwestern corner of the property. Battery manufacturing operations generated approximately 35,000 gallons of wastewater containing dilute sulfuric acid and lead (D002 and/or D008 waste) per day. Process wastewater was collected in a series of floor drains in the plant buildings and piped to the on-site treatment facility. At the treatment facility, wastewater was initially collected in a sump and pumped to one of two aboveground holding tanks for equalization. The holding tanks were located outside the treatment facility, and each tank held approximately 6,350 gallons of wastewater. From the holding tanks, wastewater was pumped into a three stage reaction tank where lime was added for pH neutralization and precipitation of lead. The reaction tank had a design capacity of 48,000 gallons.

In April 1984, an 865,700-gallon clarification tank located outside the wastewater treatment building was placed into operation and was used in the treatment scheme for solids and liquids separation. Solids consisted primarily of calcium sulfate from the lime neutralization process that had settled to the bottom of the clarification tank. Treated and clarified liquid from the clarification tank was discharged under a permit to the city sewer system. Semi-solid sludge at the bottom of the clarifier was withdrawn and pumped to a sludge tank (SWMU 2) for temporary holding prior to dewatering in a filter press. Filtrate from the sludge dewatering operations was collected and pumped back into the reaction tank for subsequent treatment. Dewatered sludge from the filter press was accumulated in a roll-off container (SWMU 6) prior to off-site transport to Adams Center Landfill for disposal. Prior to June 1986, the sludge was dewatered in a vacuum pan filter and dewatered sludge was accumulated in a waste pile (SWMU 1) in an enclosed building before being transported off site for disposal.

The aboveground wastewater treatment holding tanks were located outside on a concrete pad. The system's sump and reactor tanks were located inside the facility. There are no documented releases from either the sump or the wastewater treatment system itself. It is expected that a significant release of hazardous sludge or wastewater from this unit would have been noted in the historical file material, as it likely would have interrupted process operations at the facility.

The WWTP and sump were decontaminated and removed as part of the 2012 decommissioning activities. The areas below the sumps and clarifier were backfilled using crushed concrete rubble from the facility demolition. No evidence of a release was observed. In 2014, soil boring B-13 was performed in the vicinity of the former WWTP. Refusal was encountered at a depth of 2-feet bgs. However, the 1.5 to 2 feet deep sample interval produced a lead detection of 13,200 mg/kg.

5.5.6 SWMU-6 Filter Building

This unit was not previously assigned a SWMU number at the time of the PR/VSI, but was assigned a SWMU number as part of the 2011 USEPA letter report. This unit functioned like a baghouse during the plant's manufacturing operations. Air from inside the plant building was sucked into the filter building where dust was caught in a system of filters. The clean air was then recycled back into the plant. The filters were cleaned or replaced as necessary. Old filters were treated as hazardous waste (D008), accumulated in the hazardous waste accumulation area for less than 90 days, and sent to a secondary lead smelter in Pennsylvania for recycling. Lead-contaminated dust (D008 waste) from the filters was collected in 55-gallon drums that were also accumulated in the hazardous waste accumulation area for less than 90 days and transported to a secondary lead smelter in Pennsylvania for recycling.

The filter system was totally encapsulated and there are no documented releases from the unit. Old filters were shrink-wrapped in plastic before being placed on pallets to prevent residual dust from falling off the used filters. It is assumed that this unit was regulated by the IDEM operating permit (#16313) which governed air emissions and was closed when facility operations ceased. The Filter Building was decontaminated and demolished during the 2012 decommissioning project. Masonry block from the building was crushed and reused onsite as fill material.

5.5.7 SWMU-7 Roll-off Container

This unit was not previously assigned a SWMU number at the time of the PR/VSI, but was assigned a SWMU number the 2011 USEPA letter report. This unit was a roll-off container located indoors beneath the filter press. This unit was used for less than 90-day accumulation of dewatered wastewater treatment sludge carrying the D008 hazardous waste code until that waste was transported off site for disposal. It is estimated that use of the SWMU 7 roll-off container for collection of dewatered sludge ended in 1997, when battery manufacturing operations ceased at the Exide facility.

This unit was located inside the plant building on a concrete floor. The PR/VSI indicated that the facility was practicing good housekeeping and no concerns with this unit were identified in compliance inspections conducted at the facility. As a result, environmental releases are unlikely. Accordingly, there are no documented releases from this unit. The roll-off container was removed from the Facility prior to the 2012 decommissioning project.

5.5.8 SWMU-8 Former Waste Pile #2

This unit did not exist at the time of the 1988 PR/VSI, but was assigned a SWMU number for purposes of the 2011 USEPA letter report. This unit was a 30-foot by 30-foot waste pile formerly located in the northeast potion of the facility. The waste pile contained lead-contaminated soil that was reportedly excavated during the course of a remodeling project conducted at the facility in 1996. Approximately 123 cubic yards of lead-contaminated soil were placed directly on the ground surface at this unit. All wastes managed in the waste pile were removed from the area and disposed at a permitted off-site TSD facility in February 1996. An additional 6 inches of soil beneath the waste pile was also removed during this operation. Reportedly, there were no indications of spillage or run-off outside the defined 30-foot by 30-foot pile footprint. Sampling, characterization, and removal of wastes and soil were conducted by Clean Harbors of Chicago, Illinois.

The waste pile came to the attention of IDEM during a routine CEI conducted in June 1997. Following the inspection, IDEM issued a NOV to Exide for creating a hazardous waste pile without a permit and for failure to meet the general requirements for a waste pile such as run-on/run-off management, wind dispersal controls, and leachate collection. On July 1998, Exide entered into an AO with IDEM to resolve issues arising from the inspection and resulting NOV.

Exide collected soil samples from four soil borings advanced within the former waste pile footprint and analyzed the soil samples for total lead in August 1998. The soil samples were collected every 6 inches to a depth of 3 feet bgs, and then again at 4 feet bgs and at 5 feet bgs, for a total of 24 samples. Total lead concentrations ranged from 11 to 3,800 mg/kg. The concentrations decreased with depth before increasing in fill materials near the 5-foot depth. Based on the sampling results, IDEM directed Exide to submit a closure plan for the hazardous waste pile. The Closure Plan and Addendas No. 1, 2, and 3 were approved by IDEM in March 2000.

On March 22, 2000, Exide conducted soil sampling to establish background lead concentrations for shallow fills in the vicinity of the former waste pile in accordance with Addendum No. 3 to the hazardous waste pile closure plan. Six soil samples were collected of fill materials to a maximum depth of 18 inches bgs and analyzed for total lead. Total lead concentrations ranged from 165 to 2,970 mg/kg. In November 2000, Exide removed a uniform layer of 18 inches of soil in an area with dimensions of 40 feet by 40 feet in accordance with the approved closure plan. The excavation area was expanded by 5 feet on each side of the original footprint of the waste pile. No confirmatory samples were collected at the bottom of the excavation because previous sampling events in the proposed excavation area indicated that lead levels below 18 inches bgs were below the RISC Tier 1 Residential values (400 mg/kg). However, lead levels at approximately 5 feet bgs increased to levels above RISC Tier 1 Residential values.

On November 8, 2000, the excavation was backfilled with clean soil imported from Paddock Brothers, Inc. of Frankfort, Indiana. The excavated soils were characterized as hazardous for lead prior to disposal. Approximately 246 tons of excavated materials were treated such that leachable levels of lead were below RCRA TCLP concentrations and disposed at Max Environmental Inc.'s Mill Services TSD facility in Yukon, Pennsylvania. Exide submitted the Hazardous Waste Pile

Closure Report to IDEM on January 9, 2001. IDEM approved the closure report on February 14, 2001.

It is not clear whether increasing lead concentrations detected in the fill at 5 feet bgs are isolated to this location or if fill is present at greater depths in other portions of the Site. Soil samples collected from the 2014 investigation boring B-4 in this portion of the Site had low concentrations of lead (< 23.7 mg/kg).

5.5.9 SWMU-9 Parts Cleaners

This unit was not documented in the PR/VSI, but was assigned a SWMU number in the 2011 USEPA letter report. This unit consisted of two parts cleaners located in the maintenance area in the basement of the plant building. The parts cleaners generated waste naphtha, which was disposed off-site by Safety-Kleen. Inspections conducted in 2001 and 2010 did not mention the presence of the parts cleaners on site.

The parts cleaners were located inside the plant building on concrete slab. Spilled material would have been contained by the building. Moreover, because the waste naphtha was a valuable recyclable commodity, it would have made economic sense for both Exide and Safety-Kleen to ensure unit integrity and promptly clean up and containerize any waste naphtha that was spilled. There are no documented releases from this unit.

5.5.10 AOC-1 Loading Dock Area

This AOC was identified by IDEM during a RCRA Compliance Inspection conducted on April 3, 1986. On July 18, 1986, IDEM issued General Battery an NOV (V-137) for depositing waste from spent batteries on the ground in the battery loading area. The loading dock was used for loading spent batteries. The area of contamination was a 35-foot by 45-foot area located east of the loading dock.

On January 19, 1988, Exide collected 32 soil samples in a 10-foot grid pattern throughout the 35-foot by 45-foot area east of the battery loading dock. Soil samples were randomly collected at depths up to 5 feet to support determination of background lead and cadmium concentrations in soil. Lead concentrations ranged from 12 to 9,300 mg/kg, and cadmium concentrations ranged from 0.11 to 13 mg/kg. Six samples were also analyzed for leachable levels of lead and cadmium, as measured using TCLP. TCLP lead concentrations ranged from 2.4 to 15 mg/L. TCLP concentrations greater than 5.0 mg/L of lead are considered characteristic hazardous waste (D008). The TCLP cadmium concentrations ranged from non-detect (ND) to 0.02 mg/L, which were below the TCLP regulatory level of 1.0 mg/L for cadmium.

Based on the sampling results, Exide proposed to excavate the 35-foot by 45-foot area to a depth of 6 inches bgs and collect confirmation samples to ensure that the cleanup level of 2,000 mg/kg for lead was successfully achieved. However, IDEM disagreed with the proposed 2,000 mg/kg cleanup level and required that a site-specific cleanup standard be established based on the mean range of a minimum of three background samples collected at least 100 feet from any roadway or process area. In November 1988, IDEM met with Exide to identify appropriate background sample locations. On July 17, 1989, IDEM informed Exide that the site-specific cleanup level would be 78 mg/kg for lead based on the results of the background samples collected by Pollution Control Systems, Inc. In a meeting at the site on July 18, 1989, IDEM and Exide agreed to excavate 1 foot of soil from the surface of the 35-foot by 45-foot spill area and apply a lime buffer to the bottom of the excavation before backfilling to control pH. In August 1992, IDEM issued a notice of compliance for NOV (V-327), which included the area now designated as AOC 1.

5.5.11 AOC-2 Castings/Grid Building Area

This AOC was identified by IDEM during a RCRA Compliance Inspection conducted on April 3, 1986. On July 18, 1986, IDEM issued General Battery a NOV (V-137) for depositing oil-contaminated boiler blow-down waste on the ground next to the castings/grid building. During the inspection, oil spillage was noted on the railroad tracks outside of the casting department. According to a facility employee, the oil was from air compressor blow-out. The outfall pipe for "chiller water" was in the same area. Water from the outfall pipe flowed approximately 500 feet

through the area and into a loading dock drain. No information was obtained during the development of this CCR as to where the drain discharged.

The oil-contaminated boiler blow-down waste was released to the ground. Consequently, there were no release controls for this AOC. In response to the July 1986 NOV, the facility collected a sample of waste from the stained area, and then excavated soil in the stained area to a depth of approximately 2 feet bgs, where the soil was no longer visibly stained. The facility collected a soil sample at the bottom of this excavation. Both samples were analyzed for lead, cadmium, oil, and grease. Information regarding the excavation was submitted to IDEM in January 1987.

In a Notice of Inadequacy dated March 27, 1987, IDEM requested further explanation for the 2-foot depth of excavation and asked that the samples of excavated materials also be analyzed for PCBs and total halides. In response to the Notice of Inadequacy, the facility collected another sample of the excavated material and a confirmatory soil sample at the 2-foot depth of the excavation. The samples were analyzed for PCBs and total halides, but no data were found in the available file material during preparation of this CCR.

The facility provided a response letter dated May 29, 1987 which expressed that based on phone conversations with IDEM an excavation to a depth where soil was not visibly stained was sufficient.

Exide also indicated that, based on the analytical results, they planned to dispose of the excavated material as non-hazardous, special waste in a RCRA landfill approved by IDEM.

In August 1992, IDEM issued a notice of compliance for violations associated with AOC 2, including the release of oil-contaminated boiler blow-down waste in the Castings/Grid Building Area.

In 2014 soil boring B-11 was performed in the former grid casting area to a depth of 3 feet. Lead detections in five samples collected ranged from 203 mg/kg in the 0-0.5 feet interval to 9.9 mg/kg at the 2.5-3 feet depth interval. Soil boring B-12 was performed in the former parts casting area to a depth of four feet in five samples collected, the maximum detection was 13.3 mg/kg.

5.5.12 AOC-3 Underground Petroleum Storage Tanks

In 1987, the facility had three active USTs: a 20,000-gallon #2 fuel oil tank located on the north side of the facility, a 10,000-gallon diesel tank located in the southeast side of the facility, and a 10,000-gallon #2 fuel oil tank located on the southwest side of the facility.

On March 2, 1987, as a follow-up to a citizen complaint, ERB filed an Incident Report indicating that fuel oil had been detected in a residential basement and two storm sewer manholes in close proximity to the General Battery facility, including the 20,000-gallon fuel oil tank located approximately 50 feet from an affected manhole. As a result of the incident, ERB requested that Exide perform tightness testing on its three USTs. Tightness testing was conducted on March 4, 1987, and all three tanks failed the tightness criteria of± 0.05 gallons of leakage per hour. Based on these results and the fact that the UST was the nearest facility tank to the complainant's house, Exide decided to close the 20,000-gallon #2 fuel oil UST in April 1987. However, the facility did not agree that the fuel oil UST was the source of the release.

According to a letter from Exide's legal counsel dated October 6, 1997, the 20,000-gallon fuel oil UST (UST-3) was closed in place in April 1987, in accordance with Indiana Fire Marshall regulations in effect at that time. During closure, the UST was emptied of residual fuel oil, cleaned, inspected by the Fire Marshall, and filled with clean fill. According to the maintenance supervisor, no evidence of release was observed during the tank closure.

In addition, the 10,000-gallon diesel tank (UST-2) was permanently taken out of service in December 1991 and removed in April 2014. During and following the removal low level detections of chlorinated solvents and naptha compounds were observed in surrounding soils

(exceeding 2014 IDEM RISC MTG screening levels) and groundwater (exceeding 2014 IDEM RISC residential tap water and vapor exposure screening levels).

The 10,000 gallon #2 fuel oil tank (UST-1) was also removed in April 2014. Any remaining soil and groundwater impacts from petroleum in the vicinity of the former UST-1 location do not exceed the IDEM RISC screening criteria for direct contact or migration to groundwater scenarios. The groundwater sampled onsite around the UST-1 location does not appear to have petroleum contamination. Soil boring B-10, performed in March 2014 was located near the UST-1 location. Boring B-10 had a detection of lead at a concentration of 1,520 mg/kg in the 0.5 – 1 foot depth interval. However in other intervals going as deep as four feet, the other detections ranged from 8.4 mg/kg to 61.1 mg/kg.

Both UST-1 and UST-2 were closed through the IDEM LUST program and granted NFA-status on December 23, 2014. However, the detections of chlorinated solvents in the soils and groundwater (maximum detections of TCE 8,520 ug/L; vinyl chloride 3,590 ug/L) around UST-2 were noted as requiring additional investigation in the future. The EPA reportedly detected concentrations of TCE in an adjacent home at a concentration of 0.44 ppbv (exceeding the vapor intrusion screening limit). As a result, a vapor mitigation system was reportedly installed and is currently operating at the home to create acceptable indoor air quality inside the home.

Although the detections of the chlorinated solvents were observed during the removal of the UST located on the Exide property, interviews with a former plant manager (Appendix C) have not provided any indication that any of those compounds were used, stored, or disposed of onsite. The mechanism for introduction of these chemicals into the soil and groundwater around the former UST-2 location has not been identified.

Additional investigation of soil and groundwater in the vicinity of UST-2 is needed to determine the extent of contamination as well to identify/confirm an onsite or offsite source. Investigation to confirm the location of UST-3 and any potential impacts is also recommended.

6.0 HISTORIC INVESTIGATIONS AND DATA

Exide has performed sampling of site soils in various locations. The available data which is still considered relevant to current conditions is summarized in the following subsections. The determination of which historic data for the Site is still relevant is largely based on whether the conditions in a given area could have changed significantly since the collection of data (e.g. "was an area subject to excavation or disturbance?").

6.1 1985 MANUFACTURING AREA BORINGS

In 1985, in response to an inspection/request by the Indiana State Board of Health, Exide performed soil testing in five (5) borings (Borings S-1 through 5) within the manufacturing area. Borings were typically performed to a depth of 8.5 feet with samples collected at two foot intervals. Borings were performed in a transformer room (S-1), an acid storage area which would later become New Formation (S-2), the north side of the Old Formation area (S-3), Outside of Pasting (S-4, not marked on a drawing), and Wet Formation (S-5). Data for soil pH, and TCLP Cadmium, TCLP lead, and TCLP selenium indicates that soil pH was generally neutral to alkaline and non-leaching. The 0.5 foot depth sample from location S-4 had a TCLP lead result of 5.1 mg/L, narrowly exceeding the RCRA hazardous standard. Only one other sample had TCLP detections for lead (0.06 mg/L).

It is believed that total lead samples were also collected, however records of the data have not been located. An internal letter dated June 15, 1987 indicates that a sample from "outside pasting" had a concentration of 39% lead. This could correspond to the TCLP result at the shallow S-4 location. Data from this sampling event is provided in Appendix I.

6.2 1988 LOADING DOCK SOIL SAMPLES

In January 1988, Exide performed soil sampling at the area immediately east of the loading dock. Twenty-three (23) soil borings were performed to depths of up to 5.0 feet bgs. Thirty-two (32) samples were collected and analyzed for total lead and Cadmium. The majority of the samples were collected from the 0-0.5 foot and 0.5-1.0 foot depth intervals.

The highest lead detection was 9,300 mg/kg in the 0-0.5 foot depth interval. Eleven (11) samples exceeded the IDEM RISC direct contact screening level of 400 mg/kg; eight (8) of which also exceeded the non-residential screening level of 800 mg/kg. All of these exceedances were observed in the 0-0.5 foot and 0.5-1.0 foot depth intervals.

The highest total cadmium detection was 13 mg/kg in a sample from the 0-0.5 foot depth interval (different boring from sample with highest total lead concentration). No sample results exceeded the IDEM RISC direct contact screening level of 99 mg/kg.

Six (6) samples were analyzed for TCLP. Three (3) of the samples exceeded the RCRA hazardous criteria for TCLP lead of 5.0 mg/L (highest result 15 mg/L). All three of those samples were from intervals with relatively low total lead concentrations (< 270 mg/kg). None of the samples had leachable cadmium (< 0.02 mg/L).

Soils in this area were remediated by Exide as described in Section 5.3.2. Data from this sampling event is provided in Appendix J.

6.3 HAZARDOUS WASTE PILE CLOSURE (1998 – 2000)

In August 1998, soil samples were collected from four soil borings advanced within the former waste pile footprint and analyzed for total lead. The soil samples were collected every 6 inches to a depth of 3 feet bgs, and then at 4 feet bgs and at 5 feet bgs, for a total of 24 samples. Total lead concentrations decreased with depth before increasing near the 5-foot depth interval. All samples collected from the 18 - 24 inch bgs depth interval satisfied the IDEM RISC Tier I residential

cleanup level (400 mg/kg). Brick fragments were encountered in the borings within the 4.5 - 5 foot bgs depth interval confirming the presence of fill at that depth.

In March 2000, Advanced GeoServices performed soil sampling in the vicinity of the former waste pile to establish "background conditions." Samples were collected from six borings at depths of up to 18 inches to represent the fill interval in that area. The total lead values ranged from 165 mg/kg to 2,970 mg/kg with an average of 967 mg/kg.

The sample results obtained by Advanced GeoServices confirmed that there is variability within the onsite fill materials with respect to lead concentrations. Only minor surface disturbance occurred in this area during the facility demolition in 2012. Data from this closure is provided in the report in Appendix F.

6.4 2012 FACILITY DECONTAMINATION AND DEMOLITION

After surface washing was completed, but prior to demolition, samples were collected from brick, concrete block, and other masonry materials. The samples were chipped away from the surface of the materials and used to create 5-point composite samples. A total of 5 samples were collected (Parts Casting Brick, Grid Casting Block, Burning/Pasting Brick, Send Out Brick, and Breakroom/Office Brick.

The samples were analyzed for Priority Pollutant Metals. The sample data indicated that the masonry materials were not characteristically hazardous based on TCLP results. The total concentrations of metals were also reviewed and compared to the 2012 IDEM RISC screening levels. All of the samples had metals concentrations below the industrial/commercial direct contact limits for soil exposure (maximum total lead concentration 490 mg/kg). Four of the five samples also had metals concentrations that were below the residential limits as well (180 mg/kg, 29 mg/kg, 18 mg/kg, and 9.6 mg/kg total lead respectively). Three of the samples (5.7 mg/kg, 8.5 mg/kg, and 11 mg/kg) exceeded the residential direct contact limit for arsenic. Sample results are provided on Table 3.

As the demolition of the structures progressed, the masonry materials were segregated and stockpiled. The masonry was broken up by running over it with heavy equipment. Typically, the maximum dimension of the crushed masonry was less than 8-in. Approximately 3,300 CY of masonry rubble material was generated and was later used as backfill onsite at locations shown on Figure 3.

6.5 2014 SOIL BORINGS

In March 2014, a site-wide soil investigation was performed by Exide. The 27 soil boring locations were selected to cover each of the former operational departments/locations (Oxide, Formation, etc.) as well as broader coverage of the Site (yards, lots and outlying areas). The attached Figure 5 depicts the location of each boring. This data set represents the most current and inclusive total lead data for the Site.

Typically, the total depth of the borings was 4 feet below the ground surface (or below the bottom of pavement/concrete); however, in some cases poor recovery resulted in shallower depth. At eight (8) locations, the total depth of the borings was 8-ft. The 8-ft deep borings were completed in locations with a higher potential for deeper migration of contaminants.

At each boring, samples were collected from the 0-6" interval, the 6"-12" interval, and then the bottom 6" of each 1-ft interval thereafter (i.e., 18"-24", 30-36", 42-48", etc.). In some cases if soil conditions changed dramatically, a sample was collected at an alternate 6" interval. Samples were analyzed by Pace Analytical of Indianapolis for lead using method 6010B. A silty clay soil was observed in the majority of the boring locations. At locations B3, B9, and B13 a sandy fill material was encountered. This was expected at location B3 since it is near an elevated railroad embankment. Exide indicates that fill was placed beneath the Old Formation area where B9 was collected. It is also likely that fill or grading was performed during the construction of the former water treatment building where B13 was located. None of the fill material encountered in these borings was waste like in nature.

Each sample interval was field screened for total volatile organic compounds (TVOCs) using a photo-ionizing detector (PID). PID measurements ranged from 0 to 9.5 ppmV. The average of all TVOC measurements was approximately 2.1 ppmV. No oily sheens, organic or petroleum odors were noted. These observations indicate organic/petroleum impacts are not present. Soil conditions were damp in many locations, but no clearly identifiable groundwater surface was encountered.

Analytical results of soil samples collected as part of this investigation are provided on the attached Table 4. The table compares the lead results to the IDEM RISC Screening Levels. The residential screening level for lead in soil is 400 mg/kg. The commercial/industrial screening level for lead in soil is 800 mg/kg.

One hundred and seventy one (171) soil samples were collected and analyzed (including field duplicates). One hundred thirty-eight (138) samples were below all direct contact screening levels. Fifteen (15) samples, representing fourteen (14) boring locations, had lead results in excess of the commercial/industrial screening level.

No exceedance of the commercial/industrial screening level was observed in sample intervals deeper than 1.5-2'. This data confirms what would be anticipated, given leads extremely low solubility. In all but one location where an exceedance of the commercial/industrial screening level was detected, the next deeper sample interval had lead results below the commercial/industrial screening level. The sole exception is at location B-13, where poor recovery was experienced and the result of 13,200 mg/kg in the 1.5-2' sample interval represents the deepest sample obtained.

A copy of the letter summarizing this sample event is provided in Appendix D.

6.6 2014 UST REMOVAL

Data collected during the 2014 UST removal reflects the only recent non-lead/metals data for soil onsite. It is also includes the only groundwater data from the Site.

6.6.1 UST-1

The final post-excavation soil sample results were compared to IDEM 2014 RISC residential direct contact screening limits as well as the soil migration to groundwater values. The laboratory results for soils remaining after the excavation (post-excavation soil samples) are summarized on Table 5A.

The groundwater samples taken from each boring location were compared to the IDEM 2014 RISC screening levels for residential tap water and (potential) vapor exposure from groundwater. None of the groundwater sample results exceeded the IDEM 2014 RISC screening levels. These groundwater results are shown on Table 5B.

Post-excavation soil samples collected in the vicinity of the former UST-1 location do not exceed the IDEM RISC screening criteria for direct contact or migration to groundwater scenarios. The groundwater samples collected around UST-1 were all below detection for VOCs.

6.6.2 UST-2

The post excavation soil sample results were compared to IDEM 2014 RISC residential direct contact screening limits as well as the migration to groundwater values. The laboratory results are summarized on Table 6A. None of the post excavation sidewall or bottom samples exceeded the direct contact limits. Samples collected from the bottom of the excavation were typically at a nominal depth of 12-ft bgs. Samples collected from sidewall locations were collected at the mid-depth of the excavation sidewall; typically 6-ft bgs.

The samples collected from the bottom of the excavation, UST2-BW and UST2-BE had exceedances of the migration to groundwater standard for vinyl chloride (VC). Two samples associated with the exploratory trenches at the adjacent Fuel Storage Area, FS-N1 and FS-W1 had exceedances of the migration to groundwater standard for naphthalene. The sidewall sample collected at FS-W1 also had an exceedance of the migration to groundwater standard for 1-methylnapthalene. However, additional samples that were collected from the trenches further

away from the UST-2/FS excavation at locations FS-N2 and FS-W2 did not produce any exceedances. These analytical results are summarized on Table 6A. The locations of the highest exceedances are summarized on Figure 6.

The soil results for the ISC investigation event were also compared to the IDEM 2014 RISC screening limits for residential direct contact. No contaminants were detected at concentrations exceeding the direct contact limits. However, at each of the three locations (4 soil samples) various chlorinated solvents were detected at concentrations that exceed the migration to groundwater screening limit.

- At location UST2-A, the sample collected from the 10-ft to 12-ft depth interval had concentrations of cis-1,2-DCE, TCE, and VC which exceed the migration to groundwater screening limit.

- At location UST2-B, the sample collected from the 10-ft to 12-ft depth interval had concentrations of VC which exceed the migration to groundwater screening limit.

- At location UST2-C, the sample collected from the 3-ft to 4-ft depth interval had concentrations of naphthalene, 1-methylnaphthalene, and 2-methylnaphthalene which exceed the migration to groundwater limit. The soil sample collected from the 15-ft to 16-ft depth interval had a concentration of VC which exceeds the migration to groundwater standard.

The groundwater/surface water sample collected during the UST removal and over-excavation events were compared to the RISC screening limits for residential tap water. Both of the samples had exceedances for Naphthalene and VC. The more recent sample (May 7, 2014) had additional exceedances for cis-1,2-DCE, trans-1,2-DCE and trichloroethene. The UST-2 groundwater analytical results can be found in Table 6B.

The groundwater samples collected from each boring location were compared to the IDEM 2014 RISC screening levels for residential tap water and [potential] vapor exposure from groundwater. The groundwater sample collected at the UST2-A location had concentrations that exceed the residential tap water standard for DCA, 1,1-DCE, cis-1,2-DCE, TCE and VC; the concentrations of 1,1-DCA, TCE, and VC also exceed the screening limits for potential vapor exposure.

Groundwater sampled at the UST2-B and UST2-C locations also had concentrations that exceed the residential tap water screening limit for cis-1,2-DCE and VC; the VC results also exceed the screening limit for potential vapor exposure. All analytical results can be found in Table 6B, exceedances and general locations are depicted on Figure 6.

7.0 CONTAMINANTS OF CONCERN

7.1 INORGANIC COMPOUNDS

Lead is the primary inorganic contaminant that has been observed on the Site. This is consistent with long term use of the Site for the manufacture of lead-acid batteries. Typically other related metals such as arsenic and cadmium may also be observed at the site of a former battery manufacturing operation. However, these other metal contaminants are typically present in conjunction with lead and not instead of lead. As a result, lead typically remains the driver for investigation, risk assessment, and remediation planning.

Other anthropogenic sources of lead on the Site could be attributed to emissions from combustion of leaded gasoline and the use of lead paint.

7.1.1 Lead (Pb)

Lead is a heavy, ductile, and soft gray metal. Lead is soluble in nitric acid, insoluble in water, and dissolves slowly in weaker acids. Lead is one of the major components of lead-acid batteries. Lead is commonly found in ionic form in both the waste water and acids used during battery manufacture. The human toxicological effects of lead result from its adverse effect on the central nervous system, peripheral nerves, the kidneys, and the hematopoietic system. Lead is toxic by ingestion and inhalation of dust or fumes.

2017 IDEM RISC Screening Levels for Lead:

- Soil Residential Direct Contact: 400 mg/kg
- Soil Com/Industrial Direct Contact: 800 mg/kg
- Soil Excavation Direct Contact: 1,000 mg/kg
- Soil Migration to Groundwater: 270 mg/kg
- Residential Tap Water: 15 ug/L

7.1.2 Arsenic (As)

Arsenic is a gray, non-metallic element commonly used in the hardening of copper and lead alloys and their components. As a pure element, arsenic is insoluble in water; however, some arsenates are soluble. Arsenic is converted to arsenous (or arsenic acid) by hot sulfuric acid. Arsenous is freely soluble in water. Arsenic occurs in ionic form in lead-acid batteries. Arsenic is a human carcinogen and most compounds formed by arsenic are highly toxic.

2017 IDEM RISC Screening Levels for Arsenic:

- Soil Residential Direct Contact: 9.5 mg/kg
- Soil Com/Industrial Direct Contact: 30 mg/kg
- Soil Excavation Direct Contact: 920 mg/kg
- Soil Migration to Groundwater: 5.9 mg/kg
- Residential Tap Water: 10 ug/L

During previous work in Indianapolis, Advanced GeoServices has noted background arsenic concentrations of 12.7 mg/kg in native soils.

7.1.3 Cadmium (Cd)

Cadmium is a soft, white metallic element that is soluble in acids. Cadmium is commonly used I small amounts to lower the melting point of alloys. Cadmium is used in the production of lead allots and is generally found in ionic form in lead-acid batteries. Cadmium is a carcinogen and soluble compounds of cadmium are highly toxic.

2017 IDEM RISC Screening Levels for Cadmium:

- Soil Residential Direct Contact: 99 mg/kg
- Soil Com/Industrial Direct Contact: 980 mg/kg
- Soil Excavation Direct Contact: 1,900 mg/kg

- Soil Migration to Groundwater: 7.5 mg/kg
- Residential Tap Water: 5 ug/L

7.2 NAPTHA COMPOUNDS

Petroleum-derived fuels such as gasoline, #2 heating oil, and diesel fuel were stored onsite in underground storage tanks. Fuel oils are complex structures composed of varying fractions of alkanes, aromatic hydrocarbons, sulfur, nitrogen, and oxygenated compounds. Several of the organic compounds that are typically associated with these fuels include "naphtha compounds." Naphtha compounds include several simple polycyclic aromatic hydrocarbons (PAHs) and were identified onsite during the closure of UST-1 and UST-2.

Naphtha compounds that were identified above the IDEM RISC soil MTG screening limit in post-excavation samples collected from the UST-2 excavation include: naphthalene, 1-methylnaphthalene, and 2-methylnaphthalene.

7.2.1 Naphthalene

Naphthalene is the simplest (PAH). It is a white crystalline solid with a characteristic odor that is detectable in air at concentrations as low as 0.08 ppm (by mass) and in water at concentrations of 0.021 ppm. It's most well-known application is traditional moth balls.

Most naphthalene is derived from coal tar (it is the most abundant component of coal tar). In the past (1960s – 1990s) naphthalene was also produced during petroleum refining. It is mainly used as a precursor to other chemicals such as azo dyes or phthalic anhydride (eventually used to make plasticizers). Naphthalene vapors are flammable and it is a component of fossil fuels.

Exposure to large amounts of naphthalene may damage or destroy red blood cells.

Naphthalene was detected in remaining soils in the vicinity of the UST-2 removal at a maximum concentration 0.311 mg/kg; it was not detected in groundwater samples after UST-2 removal.

2017 IDEM RISC Screening Levels for naphthalene:

- Soil Residential Direct Contact: 53 mg/kg
- Soil Com/Industrial Direct Contact: 170 mg/kg
- Soil Excavation Direct Contact: 3,100 mg/kg
- Soil Migration to Groundwater: 0.11 mg/kg
- Residential Tap Water: 1.7 ug/L
- Groundwater Residential Vapor Exposure: 110 ug/L
- Groundwater Com/Industrial Vapor Exposure: 460 ug/L

7.2.2 1-Methylnaphthalene and 2-Methylnaphthalene

1-Methylnaphthalene and 2-methylnaphthalene are related to naphthalene. They are chemically similar with the difference being the position of the methyl group on the molecule. They are used to make dyes and resins. 1-Methlynaphthalene is a clear liquid. 2-Methylnaphthalene is a white solid. Little is known about the behavior of these compounds in the environment. However it is generally accepted that they will behave similarly to naphthalene.

1-Methylnaphthalene and 2-Methylnaphthalene was detected in remaining soils in the vicinity of the UST-2 removal at maximum concentrations of 4.11 mg/kg and 3.81 mg/kg, respectively. Neither compound was detected in groundwater samples after UST-2 removal.

2017 IDEM RISC Screening Levels for 1-methylnaphthalene:

- Soil Residential Direct Contact: 250 mg/kg
- Soil Com/Industrial Direct Contact: 390 mg/kg
- Soil Excavation Direct Contact: 390 mg/kg
- Soil Migration to Groundwater: 1.2 mg/kg
- Residential Tap Water: 11 ug/L
- Groundwater Residential Vapor Exposure: NA

- Groundwater Com/Industrial Vapor Exposure: NA

2017 IDEM RISC Screening Levels for 2-methylnaphthalene:

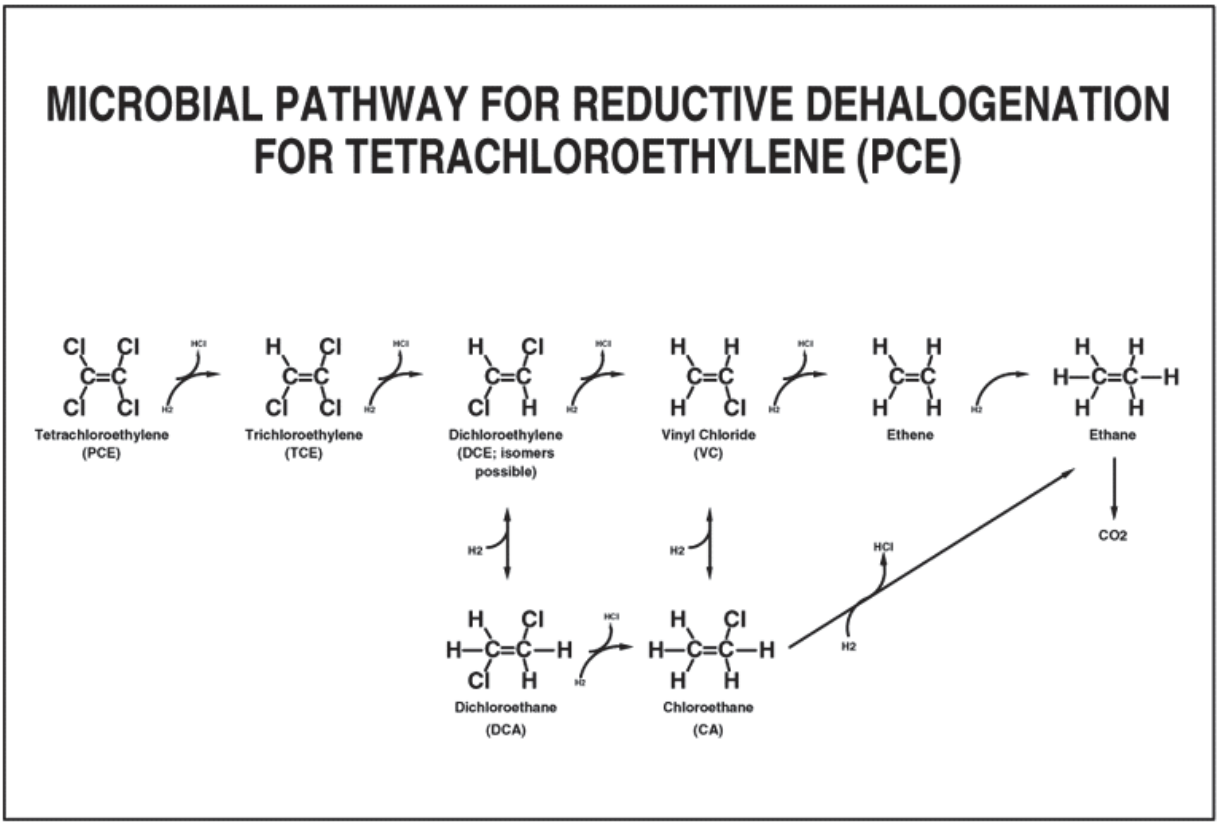
- Soil Residential Direct Contact: 340 mg/kg
- Soil Com/Industrial Direct Contact: 3,000 mg/kg
- Soil Excavation Direct Contact: 6,800 mg/kg
- Soil Migration to Groundwater: 3.7 mg/kg
- Residential Tap Water: 36 ug/L
- Groundwater Residential Vapor Exposure: NA
- Groundwater Com/Industrial Vapor Exposure: NA

7.3 CHLORINATED SOLVENTS

Chlorinated solvents have properties that make them useful for degreasing fats, oils, waxes, and resins. They are widely used and have been manufactured in large quantities. No specific use of chlorinated solvents in large quantities has been identified onsite. Chlorinated solvents are not typically associated with petroleum-derived fuel compounds. However, the presence of chlorinated solvents was identified in the vicinity of the UST-2 removal.

Chlorinated solvents are generally harmful to human and ecological health. They are suspected of causing cancer and are toxic or harmful to aquatic organisms. These contaminants can be present in the subsurface in the form of non-aqueous phase liquids (NAPL, free product), as dissolved contaminants in groundwater, within sediments in the aquifer, and as vapors in the unsaturated zone. The density of chlorinated solvents is greater than water so they tend to sink in groundwater systems (DNAPL).

Microbial degradation of chlorinated solvents can occur whereby the breakdown of parent compounds results in daughter compounds. It is common to see varying concentrations of multiple chlorinated solvents at a given location depending on the original parent product and the level of microbial degradation that has occurred.



7.3.1 Tetrachloroethylene (PCE)

PCE has not been identified onsite to date. PCE is widely used for dry cleaning and often is referred to as "dry cleaning fluid". It has a sweet odor detectable at concentrations as low as 1 part per million (ppmv). It is also used as a solvent to degrease metal parts in automotive and other metalworking industries where it is usually mixed with other chlorocarbons. It is also used in some consumer products such as paint strippers and spot removers. It was also used in the manufacturing of refrigerants at one time.

7.3.2 Trichloroethylene (TCE)

In general industry, TCE was widely used in the dry cleaning industry until it was by PCE in the 1950s. It has also been used to extract vegetable oils from plants and as an anesthetic. However,

the greatest use of TCE is as a degreaser for metal parts and in the manufacture of fluorocarbon refrigerants. TCE is a daughter product of the microbial degradation of PCE.

TCE is not known to have been used or stored onsite in small or large quantities. TCE has been detected in soil (0.135 mg/kg) and groundwater (8,520 ug/L) onsite in the vicinity of UST-2.

2017 IDEM RISC Screening Levels for TCE:

- Soil Residential Direct Contact: 110 mg/kg
- Soil Com/Industrial Direct Contact: 170 mg/kg
- Soil Excavation Direct Contact: 170 mg/kg
- Soil Migration to Groundwater: 0.045 mg/kg
- Residential Tap Water: 5 ug/L
- Groundwater Residential Vapor Exposure: 110 ug/L
- Groundwater Com/Industrial Vapor Exposure: 470 ug/L

7.3.3 1,1-Dichloroethane (1,1-DCA)

1,1-DCA is produced industrially in large volumes as a feed stock for chemical synthesis. It is also used as a solvent for plastics, oils and fats; and as a degreaser. It is also used as a fumigant in insecticide sprays, halon fire extinguishers, and in rubber cement.

1,1-DCE is not specifically known to have been used onsite in large or small quantities. 1,1-DCA is a daughter product of the microbial degradation of TCE. 1,1-DCA has been detected in onsite groundwater (61.1 ug/L) in the vicinity of UST-2.

2017 IDEM RISC Screening Levels for 1,1-DCA:

- Soil Residential Direct Contact: 50 mg/kg
- Soil Com/Industrial Direct Contact: 160 mg/kg

- Soil Excavation Direct Contact: 1,700 mg/kg
- Soil Migration to Groundwater: 0.16 mg/kg
- Residential Tap Water: 28 ug/L
- Groundwater Residential Vapor Exposure: 130 ug/L
- Groundwater Com/Industrial Vapor Exposure: 550 ug/L

7.3.4 1,1-Dichloroethene (1,1-DCE)

1,1-DCE does not have a large industrial use. Prior to 2004 it was used in the production of cling wrap (i.e., Saran wrap). Health effects from exposure to 1,1-DCE are primarily on the central nervous system. It is considered a potential occupational carcinogen by the National Institute for Occupational Safety and Health (NIOSH).

1,1-DCE has been detected in groundwater (69.4 ug/L) onsite in the vicinity of UST-2. 1,1-DCE is not specifically known to have been used onsite in large or small quantities. 1,1-DCE is a daughter product of the microbial degradation of TCE.

2017 IDEM RISC Screening Levels for 1,1-DCE:

- Soil Residential Direct Contact: 320 mg/kg
- Soil Com/Industrial Direct Contact: 1,000 mg/kg
- Soil Excavation Direct Contact: 1,200 mg/kg
- Soil Migration to Groundwater: 0.05 mg/kg
- Residential Tap Water: 7 ug/L
- Groundwater Residential Vapor Exposure: 300 ug/L
- Groundwater Com/Industrial Vapor Exposure: 1,300 ug/L

7.3.5 1,2-Dichloroethene (1,2-DCE)

1,2-DCE has two isomers: *cis*-1,2-DCE and *trans*-1,2-DCE. Both isomers are daughter products of TCE degradation and are also prevalent by-products of industrial vinyl chloride production. However 1,2-DCE is typically found as a mix of the two isomers. It is a highly flammable colorless liquid with a sharp, harsh odor. It has modest solubility in water. 1,2-DCE does not have many industrial applications. Trans-1,2-DCE is used in limited precision cleaning applications for certain metals and electronics. 1,2-DCE is not known to have been used onsite, but has been detected in groundwater onsite (cis-1,2-DCE 41,600 ug/L; trans-1,2-DCE 468 ug/L). 1,2-DCE is a daughter product of the microbial degradation of TCE.

2017 IDEM RISC Screening Levels for cis-1,2-DCE:

- Soil Residential Direct Contact: 220 mg/kg
- Soil Com/Industrial Direct Contact: 2,300 mg/kg
- Soil Excavation Direct Contact: 2,400 mg/kg
- Soil Migration to Groundwater: 0.41 mg/kg
- Residential Tap Water: 70 ug/L
- Groundwater Residential Vapor Exposure: NA
- Groundwater Com/Industrial Vapor Exposure: NA

2017 IDEM RISC Screening Levels for trans-1,2-DCE:

- Soil Residential Direct Contact: 1,900 mg/kg
- Soil Com/Industrial Direct Contact: 1,900 mg/kg
- Soil Excavation Direct Contact: 1,900 mg/kg
- Soil Migration to Groundwater: 0.62 mg/kg
- Residential Tap Water: 100 ug/L
- Groundwater Residential Vapor Exposure: NA
- Groundwater Com/Industrial Vapor Exposure: NA

7.3.6 Vinyl Chloride

Vinyl Chloride is a colorless industrial chemical that is produced in the United States on a vast scale. It is a chemical intermediate and not a final product. It is chiefly used in the production of polyvinyl chloride (PVC) plastics. Vinyl chloride is normally a gas at atmospheric temperatures and pressures. It has a sweet odor. It is highly toxic, flammable, and carcinogenic. Prior to 1974, vinyl chloride was used as an aerosol spray propellant.

Vinyl chloride is the daughter product of the microbial degradation of 1,2-DCE; and is the final chlorinated daughter product in the degradation chain. Further break down of vinyl chloride results in ethene. Vinyl chloride has been detected in remaining onsite soils at concentrations of up to 0.115 mg/kg; and in onsite groundwater at a maximum concentration of 8,520 ug/L.

2017 IDEM RISC Screening Levels for vinyl chloride:

- Soil Residential Direct Contact: 0.83 mg/kg
- Soil Com/Industrial Direct Contact: 17 mg/kg
- Soil Excavation Direct Contact: 1,300 mg/kg
- Soil Migration to Groundwater: 0.014 mg/kg
- Residential Tap Water: 2 ug/L
- Groundwater Residential Vapor Exposure: 2.1 ug/L
- Groundwater Com/Industrial Vapor Exposure: 35 ug/L

8.0 CONCEPTUAL SITE MODEL

8.1 FORMER MANUFACTURING AREAS

8.1.1 Degree and Extent

The former manufacturing areas include the former facility structures that were dedicated to battery manufacturing, offices/administration, air emission control, and wastewater treatment. The soil data that exists for the former manufacturing areas is primarily focused on potential lead contamination in shallow intervals (<4 feet below the bottom of the existing concrete floor slabs and asphalt paving). The majority of the building structures were constructed prior to the start of battery manufacturing and associated potential lead impacts. Fill materials placed beneath buildings prior to the start of battery manufacturing onsite would be expected to have relatively low concentrations of lead and other battery manufacturing-related constituents. However, lead could still be present at elevated levels in early fill materials or former surface soils from other anthropogenic sources such as emissions from the combustion of leaded gasoline or lead paint.

Although the operating record does not indicate significant potential for migration of lead into the subgrade from interior sources, it is possible that in some locations within the former manufacturing areas such migration may have occurred due to damage to facility flooring in combination with infiltration of battery acid. However, despite the severely corroded flooring in Old Formation prior to demolition in 2012; the 2014 soil boring B-9 had a maximum lead detection of only 18.5 mg/kg. TCLP data from the 1985 soil boring is also generally indicative of a lack of high concentrations of lead and other metals contaminants within the manufacturing area.

In general, the averaged data for lead in soils within the former manufacturing areas is a relatively low 243 mg/kg (below IDEM RISC soil MTG and residential direct contact screening levels). Where elevated lead concentrations are found they are concentrated within the shallow intervals (<2 feet bgs).

It should also be noted that lead is a common metal with other prevalent anthropogenic sources. It can be found at background concentrations in excess of 30 ppm in natural soils and 1 – 10 ug/L in surface water. Arsenic has also been observed naturally occurring in regional soils at levels that exceed the IDEM RISC default residential direct contact screening levels.

8.1.2 Contaminant Migration

Most lead salts are relatively insoluble in water. However, the solubility depends on pH and increases in more acidic conditions. The movement of lead in soils depends on its absorption, chelation with organic matter, and precipitation of less soluble salts. In general, lead reacts with soil anions or clays to form insoluble complexes, inhibiting mobility. Historic data indicates that even within the manufacturing area where acids were utilized the soil pH was typically neutral-alkaline.

Arsenic and cadmium are all considered insoluble inorganic constituents and their behavior in soils is generally similar to the behavior of lead. Arsenic is relatively more soluble than lead and also has an adiabatic solubility curve. Arsenic solubility decreases as pH becomes more alkaline up to a pH of approximately 9-10 (depending on the compound). At higher pH, the solubility increases again.

Lead and other inorganic contaminants that are present onsite in shallow soils are likely the result of soil mixing that resulted during construction activities which blended impacted fill materials and native soils. Spills and leaks of low pH wastewater or acids within the facility may also have facilitated the migration of lead into soils beneath paved surfaces in select locations.

Since the majority of the Site is paved and the ground water table is relatively deep, it is unlikely that lead and other inorganic contaminants have a pathway for leaching into groundwater groundwater aquifers used for water supply. However, shallow perched groundwater may be present in some portions of the Site (as observed during the UST removal). Given the silty/clayey consistency of the native soils on the site and in the region a significant vertical migration of

contaminants is not expected. Migration of inorganic contaminants via wind or stormwater runoff is also not likely.

8.2 UNDERGROUND STORAGE TANKS

8.2.1 Degree and Extent of Contamination

Following removal of UST-1 and surrounding impacted soils no petroleum related contaminants, PAHs, or chlorinated solvents were detected in soils or groundwater near the tank. UST-1 was located south of the Old Formation area. It is believed that the removal of UST-1 and impacted soils removed all or nearly all potential source materials from this area.

Following the removal of UST-2 various naptha compounds and chlorinated solvents were detected in soil at concentrations that exceeded the IDEM RISC soil MTG screening limits (but not direct contact values).

Maximum soil concentrations of remaining soil contaminants at UST-1 were:

- Naphthalene: 0.311 mg/kg
- 1-methylnaphthalene: 4.11 mg/kg
- 2-methylnaphthalene: 3.81 mg/kg
- TCE: 0.135 mg/kg
- Cis-1,2-DCE: 1.38 mg/kg
- Vinyl chloride: 0.115 mg/kg

Naphtha compounds were not detected in groundwater samples collected from the UST-2 area (20-ft offset from UST-2 location). Chlorinated solvents were also detected in groundwater at concentrations that exceeded the IDEM RISC residential tap water standard or the IDEM RISC vapor exposure screening levels at an offset of 20-feet from the UST-2 location (see section 8.4). Samples collected as part of the UST closure were collected at depths equivalent to the bottom of the UST (11-12 feet bgs) and within 20-feet from UST-2.

Maximum groundwater concentrations of remaining groundwater contaminants which exceed residential tap water screening limits at UST-2 were:

- 1,1-DCA 61.1 ug/L
- 1,1-DCE 69.4 ug/L
- Cis-1,2-DCE: 41,600 ug/L
- trans-1,2-DCE: 468 ug/L

Maximum groundwater concentrations of groundwater contaminants which exceed residential tap water screening limits and vapor exposure screening limits at UST-2 were:

- TCE: 8,520 ug/L
- Vinyl chloride: 3,590 ug/L

8.2.2 Contaminant Migration

Source material soils have been largely removed and the excavation areas are backfilled with imported stone fill. Migration or direct contact by the public with any remaining contamination associated with the former USTs is not likely. The clayey silty native soils which underlie the Site provide a natural barrier against vertical contaminant migration. USEPA has reportedly detected TCE in indoor air samples at a residence near the Site. This suggests that via groundwater (Section 8.4) TCE from an onsite source has migrated offsite or that TCE from an offsite source has migrated onsite.

8.3 OVERALL SITE SOILS

8.3.1 Degree and Extent of Contamination

Grass covered portions of the Site along Washington Avenue (north of the existing security fence) were not used for battery manufacturing activities and are not believed to have been disturbed during the operating history of the Site. Investigation of a soil mound during the March 2014 soil

investigation (B-27) did not identify lead at concentration that exceed IDEM RISC direct contact screening limits.

The grassy area north of Send Out which was associated with the Hazardous Waste Pile Closure in 2000 was also investigated by the March 2014 soil investigation (B-27) which did not identify lead exceeding IDEM RISC direct contact screening limits.

Other portions of the Site outside the manufacturing areas exhibited slightly higher concentrations of lead within the shallow subsurface interval (0-2 feet bgs) than was observed within the former manufacturing areas. This is not unexpected given that many of the non-manufacturing areas within the perimeter fence were unpaved for a significant portion of the operational history. Aerial deposition of lead from onsite and offsite sources in conjunction with the use of various fill materials could have resulted in concentration of lead in areas where stormwater collected or where past grading and soil turnover occurred.

8.3.2 Contaminant Migration

Since the majority of the Site is paved and the groundwater table is relatively deep, it is unlikely that lead and other inorganic contaminants have a pathway for leaching into groundwater. However, shallow perched groundwater may be present in some portions of the Site (as observed during the UST removal). Given the silty/clayey consistency of the native soils on the site and in the region a significant vertical migration of contaminants is not expected. Migration of inorganic contaminants via wind or stormwater runoff is also not likely.

8.4 GROUNDWATER

8.4.1 Degree and Extent of Contamination

The Site does not have an active groundwater monitoring program. The only groundwater data that exists was generated during the 2014 UST removal. Prior to the removal of UST-1 and UST-2 (and associated impacted soils) the groundwater that collected within both excavations had

detections of naptha compounds and PAHs. These contaminants were not detected in post-removal groundwater samples. Samples of groundwater collected around UST-2 had detections of various chlorinated solvents at levels that exceeded IDEM RISC screening limits for residential tap water and vapor exposure. Samples collected as part of the UST closure were collected at depths equivalent to the bottom of the UST (11-12 feet bgs) and at an offset of up to 20-feet from UST-2.

Maximum groundwater concentrations of remaining groundwater contaminants which exceed residential tap water screening limits are:

- 1,1-DCA 61.1 ug/L
- 1,1-DCE 69.4 ug/L
- Cis-1,2-DCE: 41,600 ug/L
- trans-1,2-DCE: 468 ug/L

Maximum groundwater concentrations of groundwater contaminants which exceed residential tap water screening limits and vapor exposure screening limits are:

- TCE: 8,520 ug/L
- Vinyl chloride: 3,590 ug/L

8.4.2 Contaminant Migration

The clayey silty native soils which underlie the Site provide a natural barrier against vertical contaminant migration. USEPA has reportedly detected TCE in indoor air samples at a residence near the Site. This indicates that TCE from an onsite source has migrated offsite or that TCE from an offsite source has migrated onsite.

If the source of the chlorinated solvents is onsite at the location of former UST-2 then concentrations further away from the source could be lower due to biological degradation (Section 7.3) and mixing with unimpacted groundwater.

There does not appear to be any shallow groundwater wells used for potable or non-potable water supply in the immediate vicinity of the Site based on the well search performed at the time of the UST-removal in 2014. No groundwater receptors are identified.

9.0 INTERIM CORRECTIVE MEASURES ASSESSMENT

9.1 ONSITE SOILS

All of the locations where lead has been detected above IDEM RISC direct contact screening levels are within paved areas. No exposure pathway exists for human or ecological receptors. Similarly, naphtha compounds and chlorinated solvents detected within the vicinity of UST-2, were not found at concentrations that exceed direct contact standards. The UST-2 excavation was backfilled with crushed stone and is not paved. However, there is still no exposure pathway for the soil remaining in the UST-2 excavation to be reached by the public or ecological receptors. No interim corrective measures are proposed for onsite soils.

9.2 GROUNDWATER

Chlorinated solvents such as various isomers of DCE, vinyl chloride, and TCE have been detected in groundwater onsite in 2014 at concentrations that exceed the IDEM RISC residential tap water standard. However, all properties neighboring the Site are provided with municipally supplied potable water. It is not believed that human or ecological receptors are being exposed to chlorinated solvents via groundwater ingestion. No interim corrective measures are proposed to address groundwater ingestion.

Chlorinated solvents such as TCE and vinyl chloride have been detected in groundwater onsite in 2014 at concentrations that exceed the IDEM RISC vapor exposure screening levels. It is unclear if the source of the TCE is from within the Exide Property. The USEPA reportedly performed indoor air sampling at a neighboring property in 2015 and detected TCE in the indoor air. As a result a vapor mitigation system was installed by USEPA. No interim corrective measures are proposed to address vapor intrusion from impacted groundwater on or offsite.

10.0 DATA GAPS

10.1 FORMER MANUFACTURING AREAS

The 2014 soil investigation provided many useful data points. However some follow up sampling would aid in defining the extent of contamination on the Site. A site-wide sample grid should be established to collect soil data from the fill onsite (samples collected up to 4 feet bgs, with additional depth in select locations). In grids that have existing data from 2014 (or relevant data from previous investigation work), additional sampling may not be necessary.

Additional focused sampling may also be performed within grids that contain the following features to supplement existing data and aid in decision making:

- Former sludge storage tank (SWMU 2);
- Former baghouse and filter building (SWMU 3); and,
- Former wastewater treatment plan (SWMU 5).

10.2 UNDERGROUND STORAGE TANKS

Following the removal of UST-1, UST-2, and surrounding impacted soils in 2014 it is believed that UST-related source materials have been removed. It is believed that the closure of UST-3 in April 1987 was also performed in a manner that would have removed the majority of potential source materials. However, additional subsurface investigation to formally complete the closure of UST-3 is warranted.

10.3 OVERALL SITE

The 2014 soil investigation provided many useful data points. However some follow up sampling would aid in defining the extent of contamination on the Site. A site-wide sample grid should be established to collect soil data from the fill onsite (samples collected up to 4 feet bgs, with

additional depth in select locations). In grids that have existing data from 2014, additional sampling may not be necessary.

10.4 GROUNDWATER

Only limited groundwater exists onsite and round the Site. In order to determine the full nature and extent of the chlorinated solvents on and offsite a groundwater monitoring network must be established in the northeast portion of the Site. Additional upgradient background wells and offsite wells should be installed to determine the hydraulic gradient and contaminant isoconcentrations in order to identify the source of the chlorinated solvents. Additional groundwater monitoring wells in the former manufacturing areas are not believed to be necessary.

Table 2 - Groundwater Elevations

Location	Groundwater Depth in Boring (Initial) (ft bgs)	Groundwater Depth (Perched in Boring)
UST2-A	12	3.31
UST2-B	11	2.87
UST2-C	11	NA

Initial depth to groundwater refers to depth as initially measured in a geoprobe boring, which represents the confined/undisturbed elevations.

Perched in boring depth regers to a depth that was later observed in the geoprobe boring and is assumed to represent a perched or artesian condition where groundwater is filling a void left by the boring.

Environmental Data Resources, Inc. (EDR) Aerial Photo Decade Package is a screening tool designed to assist environmental professionals in evaluating potential liability on a target property resulting from past activities. EDR's professional researchers provide digitally reproduced historical aerial photographs, and when available, provide one photo per decade.

EDR Topographic Map Library has been searched by EDR and maps covering the target property location as provided by Advanced GeoServices Corp. were identified for the years listed below. EDR's Historical Topo Map Report is designed to assist professionals in evaluating potential liability on a target property resulting from past activities. EDRs Historical Topo Map Report includes a search of a collection of public and private color historical topographic maps, dating back to the late 1800s.

EXECUTIVE SUMMARY

A search of available environmental records was conducted by Environmental Data Resources, Inc (EDR). The report was designed to assist parties seeking to meet the search requirements of the ASTM Standard Practice for Assessment of Vapor Encroachment into Structures on Property Involved in Real Estate Transactions (E 2600).

ENVIRONMENTAL RECORDS	Maximum Search Distance*	Summary: property	1/10	1/10 - 1/3
Federal NPL site list	0.333	0	0	0
Federal CERCLIS list	0.333	1	0	0

DOMINANT SOIL COMPOSITION IN GENERAL AREA OF TARGET PROPERTY

The U.S. Department of Agriculture's (USDA) Soil Conservation Service (SCS) leads the National Cooperative Soil Survey (NCSS) and is responsible for collecting, storing, maintaining and distributing soil survey information for privately owned lands in the United States. A soil map in a soil survey is a representation of soil patterns in a landscape. The following information is based on Soil Conservation Service SSURGO data.

Soil Map ID: 1

Soil Component Name:	Fincastle
Soil Surface Texture:	silt loam
Hydrologic Group:	Class C - Slow infiltration rates. Soils with layers impeding downward movement of water, or soils with moderately fine or fine textures.
Soil Drainage Class:	Somewhat poorly drained
Hydric Status:	Not hydric
Corrosion Potential - Uncoated Steel:	High
Depth to Bedrock Min:	> 0 inches
Depth to Watertable Min:	> 38 inches

Soil Layer Information

	Boundary			Classification		Saturated hydraulic conductivity micro m/sec	Soil Reaction (pH)
Layer	Upper	Lower	Soil Texture Class	AASHTO Group	Unified Soil		
1	0 inches	12 inches	silt loam	Silt-Clay Materials (more than 35 pct. passing No. 200), Silty Soils.	FINE-GRAINED SOILS, Silts and Clays (liquid limit less than 50%), Lean Clay	Max: 14.11 Min: 4.23	Max: 7.3 Min: 5.1

EXECUTIVE SUMMARY

Soil Layer Information							
	Boundary			Classification		Saturated hydraulic conductivity micro m/sec	Soil Reaction (pH)
Layer	Upper	Lower	Soil Texture Class	AASHTO Group	Unified Soil		
2	12 inches	31 inches	silty clay loam	Silt-Clay Materials (more than 35 pct. passing No. 200), Clayey Soils.	FINE-GRAINED SOILS, Silts and Clays (liquid limit less than 50%), Lean Clay	Max: 14.11 Min: 4.23	Max: 6.5 Min: 4.5
3	31 inches	59 inches	clay loam	Silt-Clay Materials (more than 35 pct. passing No. 200), Clayey Soils.	FINE-GRAINED SOILS, Silts and Clays (liquid limit less than 50%), Lean Clay	Max: 4.23 Min: 1.41	Max: 7.8 Min: 5.1
4	59 inches	70 inches	loam	Silt-Clay Materials (more than 35 pct. passing No. 200), Silty Soils.	FINE-GRAINED SOILS, Silts and Clays (liquid limit less than 50%), Lean Clay	Max: 1.41 Min: 0.07	Max: 8.4 Min: 7.4

Soil Map ID: 2

Soil Component Name: Miami

Soil Surface Texture: silt loam

Hydrologic Group: Class B - Moderate infiltration rates. Deep and moderately deep, moderately well and well drained soils with moderately coarse textures.

Soil Drainage Class: Moderately well drained

Hydric Status: Not hydric

Corrosion Potential - Uncoated Steel: Moderate

Depth to Bedrock Min: > 0 inches

Depth to Watertable Min: > 38 inches

EXECUTIVE SUMMARY

Soil Layer Information							
	Boundary			Classification		Saturated hydraulic conductivity micro m/sec	Soil Reaction (pH)
Layer	Upper	Lower	Soil Texture Class	AASHTO Group	Unified Soil		
1	0 inches	7 inches	silt loam	Silt-Clay Materials (more than 35 pct. passing No. 200), Silty Soils.	FINE-GRAINED SOILS, Silts and Clays (liquid limit less than 50%), Lean Clay	Max: 14.11 Min: 4.23	Max: 7.3 Min: 5.6
2	7 inches	31 inches	clay loam	Silt-Clay Materials (more than 35 pct. passing No. 200), Clayey Soils.	FINE-GRAINED SOILS, Silts and Clays (liquid limit less than 50%), Lean Clay	Max: 14.11 Min: 4.23	Max: 7.3 Min: 5.1
3	31 inches	35 inches	loam	Silt-Clay Materials (more than 35 pct. passing No. 200), Clayey Soils.	FINE-GRAINED SOILS, Silts and Clays (liquid limit less than 50%), Lean Clay	Max: 14.11 Min: 4.23	Max: 7.8 Min: 6.6
4	35 inches	59 inches	loam	Silt-Clay Materials (more than 35 pct. passing No. 200), Silty Soils.	FINE-GRAINED SOILS, Silts and Clays (liquid limit less than 50%), Lean Clay	Max: 1.41 Min: 0.07	Max: 8.4 Min: 7.4

Soil Map ID: 3

Soil Component Name: Treaty

Soil Surface Texture: silt loam

Hydrologic Group: Class B - Moderate infiltration rates. Deep and moderately deep, moderately well and well drained soils with moderately coarse textures.

Soil Drainage Class: Poorly drained

Hydric Status: All hydric

Corrosion Potential - Uncoated Steel: High

Depth to Bedrock Min: > 0 inches

Depth to Watertable Min: > 15 inches

EXECUTIVE SUMMARY

Soil Layer Information							
	Boundary			Classification		Saturated hydraulic conductivity micro m/sec	Soil Reaction (pH)
Layer	Upper	Lower	Soil Texture Class	AASHTO Group	Unified Soil

1	0 inches	9 inches	silt loam	Silt-Clay Materials (more than 35 pct. passing No. 200), Silty Soils.	FINE-GRAINED SOILS, Silts and Clays (liquid limit less than 50%), Lean Clay	Max: 14.11 Min: 4.23	Max: 7.3 Min: 5.1
2	9 inches	33 inches	clay loam	Silt-Clay Materials (more than 35 pct. passing No. 200), Clayey Soils.	FINE-GRAINED SOILS, Silts and Clays (liquid limit less than 50%), Lean Clay	Max: 14.11 Min: 4.23	Max: 6.5 Min: 5.1
3	33 inches	38 inches	sandy clay loam	Silt-Clay Materials (more than 35 pct. passing No. 200), Silty Soils.	COARSE-GRAINED SOILS, Sands, Sands with fines, Silty Sand.	Max: 14.11 Min: 4.23	Max: 6.5 Min: 5.1
4	38 inches	59 inches	stratified loamy sand to sandy loam to silt loam	Silt-Clay Materials (more than 35 pct. passing No. 200), Silty Soils.	FINE-GRAINED SOILS, Silts and Clays (liquid limit less than 50%), Lean Clay	Max: 42.34 Min: 4.23	Max: 8.4 Min: 5.6

Soil Map ID: 9

Soil Component Name: Milford

Soil Surface Texture: silty clay loam

Hydrologic Group: Class B - Moderate infiltration rates. Deep and moderately deep, moderately well and well drained soils with moderately coarse textures.

Soil Drainage Class: Very poorly drained

Hydric Status: All hydric

Corrosion Potential - Uncoated Steel: High

Depth to Bedrock Min: > 0 inches

Depth to Watertable Min: > 7 inches

Soil Layer Information							
	Boundary			Classification		Saturated hydraulic conductivity micro m/sec	Soil Reaction (pH)
Layer	Upper	Lower	Soil Texture Class	AASHTO Group	Unified Soil		
1	0 inches	9 inches	silty clay loam	Silt-Clay Materials (more than 35 pct. passing No. 200), Clayey Soils.	FINE-GRAINED SOILS, Silts and Clays (liquid limit less than 50%), Lean Clay	Max: 14.11 Min: 4.23	Max: 7.3 Min: 5.6
2	9 inches	31 inches	silty clay	Silt-Clay Materials (more than 35 pct. passing No. 200), Clayey Soils.	FINE-GRAINED SOILS, Silts and Clays (liquid limit 50% or more), Fat Clay.	Max: 4.23 Min: 1.41	Max: 7.8 Min: 5.6
3	31 inches	59 inches	silt loam	Silt-Clay Materials (more than 35 pct. passing No. 200), Clayey Soils.	FINE-GRAINED SOILS, Silts and Clays (liquid limit less than 50%), Lean Clay	Max: 4.23 Min: 1.41	Max: 8.4 Min: 6.6

Soil Map ID: 10

Soil Component Name: Whitaker

Soil Surface Texture: silt loam

Hydrologic Group: Class C - Slow infiltration rates. Soils with layers impeding downward movement of water, or soils with moderately fine or fine textures.

Soil Drainage Class: Somewhat poorly drained

Hydric Status: Not hydric

Corrosion Potential - Uncoated Steel: High

Depth to Bedrock Min: > 0 inches

Depth to Watertable Min: > 38 inches

Environmental Interest/Information System:

US EPA TRIS (Toxics Release Inventory System) contains information from facilities on the amounts of over 300 listed toxic chemicals that these facilities release directly to air, water, land, or that are transported off-site.

IN-FRS (Indiana - Facility Registry System). The Indiana Department of Environmental Management (I-DEM) has implemented the Indiana-Facility Registry System (I-FRS). The I-FRS provides the interface and processes to link facility data monitored by multiple State and EPA program systems. In addition, I-FRS enables IDEM to reconcile environmental data and exchange it with EPA FRS using the electronic data exchange over the Network Node.

RCRAInfo is a national information system that supports the Resource Conservation and Recovery Act (RCRA) program through the tracking of events and activities related to facilities that generate, transport, and treat, store, or dispose of hazardous waste. RCRAInfo allows RCRA program staff to track the notification, permit, compliance, and corrective action activities required under RCRA.

Registry ID: 110032896472

Environmental Interest/Information System:

IN-FRS (Indiana - Facility Registry System). The Indiana Department of Environmental Management (I-DEM) has implemented the Indiana-Facility Registry System (I-FRS). The I-FRS provides the interface and processes to link facility data monitored by multiple State and EPA program systems. In addition, I-FRS enables IDEM to reconcile environmental data and exchange it with EPA FRS using the electronic data exchange over the Network Node.

US National Pollutant Discharge Elimination System (NPDES) module of the Compliance Information System (ICIS) tracks surface water permits issued under the Clean Water Act. Under NPDES, all facilities that discharge pollutants from any point source into waters of the United States are required to obtain a permit. The permit will likely contain limits on what can be discharged, impose monitoring and reporting requirements, and include other provisions to ensure that the discharge does not adversely affect water quality.

RCRAInfo is a national information system that supports the Resource Conservation and Recovery Act (RCRA) program through the tracking of events and activities related to facilities that generate, transport, and treat, store, or dispose of hazardous waste. RCRAInfo allows RCRA program staff to track the notification, permit, compliance, and corrective action activities required under RCRA.

RECORD SOURCES AND CURRENCY

To maintain currency of the following databases, EDR contacts the appropriate agency on a monthly or quarterly basis, as required.

Number of Days to Update: Provides confirmation that EDR is reporting records that have been updated within 90 days from the date the government agency made the information available to the public.

ENVIRONMENTAL RECORDS

PRP: Potentially Responsible Parties
Standard Environmental Record Source: Other Records
Search Distance: Property

A listing of verified Potentially Responsible Parties

Date of Government Version: 10/25/2013
Number of Days to Update: 3
Last EDR Contact :04/25/2017

Source: EPA
Telephone: 202-564-6023

RMP: Risk Management Plans
Standard Environmental Record Source: Other Records
Search Distance: Property

When Congress passed the Clean Air Act Amendments of 1990, it required EPA to publish regulations and guidance for chemical accident prevention at facilities using extremely hazardous substances. The Risk Management Program Rule (RMP Rule) was written to implement Section 112(r) of these amendments. The rule, which built upon existing industry codes and standards, requires companies of all sizes that use certain flammable and toxic substances to develop a Risk Management Program, which includes a(n): Hazard assessment that details the potential effects of an accidental release, an accident history of the last five years, and an evaluation of worst-case and alternative accidental releases; Prevention program that includes safety precautions and maintenance, monitoring, and employee training measures; and Emergency response program that spells out emergency health care, employee training measures and procedures for informing the public and response agencies (e.g the fire department) should an accident occur.

Number of Days to Update: 16
Last EDR Contact :03/17/2017
Source: Department of Environmental Management
Telephone: 317-233-4624

DEL SHWS: Deleted Commissioner's Bulletin Sites List
Standard Environmental Record Source: State and tribal - equivalent CERCLIS
Search Distance: 0.333 Mile

A listing of sites deleted/removed from the Commissioner's Bulletin List

Date of Government Version: 04/03/2008
Source: Department of Environmental Management

Number of Days to Update: 10
Telephone: 317-234-0347
Last EDR Contact :02/27/2017

DRYCLEANERS: Drycleaner Facility Listing
Standard Environmental Record Source: Other Records
Search Distance: 0.25 Mile

A list of drycleaners involved in the Indiana 5-Star Environmental Recognition Program. It is a voluntary program that ranks participating drycleaners on a scale of one to five stars. The program recognizes those drycleaners willing to do more for the environment and worker safety than the rules require. These drycleaners are going above and beyond the rules to protect the environment, their employees and their neighbors and customers.

SCP: State Cleanup Program Sites
Standard Environmental Record Source: Other Records
Search Distance: 0.333 Mile

The goals for the State Cleanup Section are to mitigate risk to human health and the environment.

Date of Government Version: 08/29/2016
Number of Days to Update: 52
Last EDR Contact :04/10/2017

Source: Department of Environmental Management
Telephone: 317-233-0068

SHWS: List of Hazardous Waste Response Sites Scored Using the Indiana Scoring Model
Standard Environmental Record Source: State and tribal - equivalent CERCLIS
Search Distance: 0.333 Mile

List of hazardous waste response sites scored utilizing the Indiana Scoring Model. The Indiana Scoring Model is a method of prioritizing, for state response actions, those hazardous substances response sites which are not on the National Priorities List. The ISM serves as the Commissioners management tool to address those sites which pose the most significant threat to human health and the environment in addition to assuring the departments resources are allocated accordingly.

VCP: Voluntary Remediation Program Site List

Standard Environmental Record Source: State and tribal voluntary cleanup sites
Search Distance: 0.333 Mile

A current list of Voluntary Remediation Program sites that are no longer confidential.

Date of Government Version: 08/22/2014
Number of Days to Update: 21
Last EDR Contact :04/10/2017

Source: Department of Environmental Management
Telephone: 317-234-0966

2020 COR ACTION: 2020 Corrective Action Program List

Standard Environmental Record Source: Other Records
Search Distance: 0.25 Mile

The EPA has set ambitious goals for the RCRA Corrective Action program by creating the 2020 Corrective Action Universe. This RCRA cleanup baseline includes facilities expected to need corrective action. The 2020 universe contains a wide variety of sites. Some properties are heavily contaminated while others were contaminated but have since been cleaned up. Still others have not been fully investigated yet, and may require little or no remediation. Inclusion in the 2020 Universe does not necessarily imply failure on the part of a facility to meet its RCRA obligations.

Date of Government Version: 04/22/2013
Number of Days to Update: 6
Last EDR Contact :02/10/2017

Source: Environmental Protection Agency
Telephone: 703-308-4044

ABANDONED MINES: Abandoned Mines

Standard Environmental Record Source: Other Records
Search Distance: 0.333 Mile

An inventory of land and water impacted by past mining (primarily coal mining) is maintained by OSMRE to provide information needed to implement the Surface Mining Control and Reclamation Act of 1977 (SMCRA). The inventory contains information on the location, type, and extent of AML impacts, as well as, information on the cost associated with the reclamation of those problems. The inventory is based upon field surveys by State, Tribal, and OSMRE program officials. It is dynamic to the extent that it is modified as new problems are identified and existing problems are reclaimed.

ECHO: Enforcement & Compliance History Information

Standard Environmental Record Source: Other Records

Search Distance: Property

ECHO provides integrated compliance and enforcement information for about 800,000 regulated facilities nationwide.

Date of Government Version: 12/11/2016
Source: Environmental Protection Agency
Number of Days to Update: 59
Telephone: 202-564-2280
Last EDR Contact :03/21/2017

EPA WATCH LIST: EPA WATCH LIST

Standard Environmental Record Source: Other Records

Search Distance: Property

EPA maintains a "Watch List" to facilitate dialogue between EPA, state and local environmental agencies on enforcement matters relating to facilities with alleged violations identified as either significant or high priority. Being on the Watch List does not mean that the facility has actually violated the law only that an investigation by EPA or a state or local environmental agency has led those organizations to allege that an unproven violation has in fact occurred. Being on the Watch List does not represent a higher level of concern regarding the alleged violations that were detected, but instead indicates cases requiring additional dialogue between EPA, state and local agencies - primarily because of the length of time the alleged violation has gone unaddressed or unresolved.

Date of Government Version: 08/30/2013

HIST FTTS: FIFRA/TSCA Tracking System Administrative Case Listing
Standard Environmental Record Source: Other Records
Search Distance: Property

A complete administrative case listing from the FIFRA/TSCA Tracking System (FTTS) for all ten EPA regions. The information was obtained from the National Compliance Database (NCDB). NCDB supports the implementation of FIFRA (Federal Insecticide, Fungicide, and Rodenticide Act) and TSCA (Toxic Substances Control Act). Some EPA regions are now closing out records. Because of that, and the fact that some EPA regions are not providing EPA Headquarters with updated records, it was decided to create a HIST FTTS database. It included records that may not be included in the newer FTTS database updates. This database is no longer updated.

Search Distance: 0.333 Mile

The State Coalition for Remediation of Drycleaners was established in 1998, with support from the U.S. EPA Office of Superfund Remediation and Technology Innovation. It is comprised of representatives of states with established drycleaner remediation programs. Currently the member states are Alabama, Connecticut, Florida, Illinois, Kansas, Minnesota, Missouri, North Carolina, Oregon, South Carolina, Tennessee, Texas, and Wisconsin.

SEMS: Superfund Enterprise Management System

Standard Environmental Record Source: Federal CERCLIS list

Search Distance: 0.333 Mile

SEMS (Superfund Enterprise Management System) tracks hazardous waste sites, potentially hazardous waste sites, and remedial activities performed in support of EPA's Superfund Program across the United States. The list was formerly know as CERCLIS, renamed to SEMS by the EPA in 2015. The list contains data on potentially hazardous waste sites that have been reported to the USEPA by states, municipalities, private companies and private persons, pursuant to Section 103 of the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA). This dataset also contains sites which are either proposed to or on the National Priorities List (NPL) and the sites which are in the screening and assessment phase for possible inclusion on the NPL.

SEMS-ARCHIVE: Superfund Enterprise Management System Archive

Standard Environmental Record Source: Other Records

Search Distance: 0.333 Mile

SEMS-ARCHIVE (Superfund Enterprise Management System Archive) tracks sites that have no further interest under the Federal Superfund Program based on available information. The list was formerly known as the CERCLIS-NFRAP, renamed to SEMS ARCHIVE by the EPA in 2015. EPA may perform a minimal level of assessment work at a site while it is archived if site conditions change and/or new information becomes available. Archived sites have been removed and archived from the inventory of SEMS sites. Archived status indicates that, to the best of EPA's knowledge, assessment at a site has been completed and that EPA has determined no further steps will be taken to list the site on the National Priorities List (NPL), unless information indicates this decision was not appropriate or other considerations require a recommendation for listing at a later time. The decision does not necessarily mean that there is no hazard associated with a given site; it only means that. based upon available information, the location is not judged to be potential NPL site.

UMTRA: Uranium Mill Tailings Sites

Standard Environmental Record Source: Other Records

Search Distance: 0.333 Mile

Uranium ore was mined by private companies for federal government use in national defense programs. When the mills shut down, large piles of the sand-like material (mill tailings) remain after uranium has been extracted from the ore. Levels of human exposure to radioactive materials from the piles are low; however, in some cases tailings were used as construction materials before the potential health hazards of the tailings were recognized.

US AIRS (AFS): Aerometric Information Retrieval System Facility Subsystem (AFS)

Standard Environmental Record Source: Other Records

Search Distance: Property

The database is a sub-system of Aerometric Information Retrieval System (AIRS). AFS contains compliance data on air pollution point sources regulated by the U.S. EPA and/or state and local air regulatory agencies. This information comes from source reports by various stationary sources of air pollution, such as electric power plants, steel mills, factories, and universities, and provides information about the air pollutants they produce. Action, air program, air program pollutant, and general level plant data. It is used to track emissions and compliance data from industrial plants.

US BROWNFIELDS: A Listing of Brownfields Sites

Standard Environmental Record Source: Other Records

Search Distance: 0.333 Mile

Brownfields are real property, the expansion, redevelopment, or reuse of which may be complicated by the presence or potential presence of a hazardous substance, pollutant, or contaminant. Cleaning up and reinvesting in these properties takes development pressures off of undeveloped, open land, and both improves and protects the environment. Assessment, Cleanup and Redevelopment Exchange System (ACRES) stores information reported by EPA Brownfields grant recipients on brownfields properties assessed or cleaned up with grant funding as well as information on Targeted Brownfields Assessments performed by EPA Regions. A listing of ACRES Brownfield sites is obtained from Cleanups in My Community. Cleanups in My Community provides information on Brownfields properties for which information is reported back to EPA, as well as areas served by Brownfields grant programs.

EDR Hist Auto: EDR Exclusive Historic Gas Stations

Standard Environmental Record Source: Historical Gas Stations

Search Distance: 0.125 Mile

EDR has searched selected national collections of business directories and has collected listings of potential gas station/filling station/service station sites that were available to EDR researchers. EDR's review was limited to those categories of sources that might, in EDR's opinion, include gas station/filling station/service station establishments. The categories reviewed included, but were not limited to gas, gas station, gasoline station, filling station, auto, automobile repair, auto service station, service station, etc. This database falls within a category of information EDR classifies as "High Risk Historical Records", or HRHR. EDR's HRHR effort presents unique and sometimes proprietary data about past sites and operations that typically create environmental concerns, but may not show up in current government records searches.

Date of Government Version: 02/20/2007

EDR MGP: EDR Proprietary Manufactured Gas Plants

Standard Environmental Record Source: Former Manufactured Gas Plants

Search Distance: 0.333 Mile

The EDR Proprietary Manufactured Gas Plant Database includes records of coal gas plants (manufactured gas plants) compiled by EDR's researchers. Manufactured gas sites were used in the United States from the 1800's to 1950's to produce a gas that could be distributed and used as fuel. These plants used whale oil, rosin, coal, or a mixture of coal, oil, and water that also produced a significant amount of waste. Many of the byproducts of the gas production, such as coal tar (oily waste containing volatile and non-volatile chemicals), sludges, oils and other compounds are potentially hazardous to human health and the environment. The byproduct from this process was frequently disposed of directly at the plant site and can remain or spread slowly, serving as a continuous source of soil and groundwater contamination.

Date of Government Version: 08/28/2009

TOPOGRAPHIC INFORMATION

USGS 7.5' Digital Elevation Model (DEM)

Source: United States Geologic Survey

EDR acquired the USGS 7.5' Digital Elevation Model in 2002 and updated it in 2006. The 7.5' minute DEM corresponds to the USGS 1:24,000- and 1:25,000-scale topographic quadrangle maps. The DEM provides elevation data with consistent elevation units and projection.

HYDROLOGIC INFORMATION

Flood Zone Data: This data was obtained from the Federal Emergency Management Agency (FEMA). It depicts 100-year and 500-year flood zones as defined by FEMA. It includes the National Flood Hazard Layer (NFHL) which incorporates Flood Insurance Rate Map (FIRM) data and Q3 data from FEMA in areas not covered by NFHL.

Source: FEMA

Telephone: 877-336-2627

Date of Government Version: 2003, 2015

NWI: National Wetlands Inventory. This data, available in select counties across the country, was obtained by EDR in 2002 and 2005 from the U.S. Fish and Wildlife Service.

HYDROGEOLOGIC INFORMATION

AQUIFLOW® Information System

Source: EDR proprietary database of groundwater flow information

EDR has developed the AQUIFLOW® Information System (AIS) to provide data on the general direction of groundwater flow at specific points. EDR has reviewed reports submitted to regulatory authorities at select sites and has extracted the date of the report, hydrogeologically determined groundwater flow direction and depth to water table information.

GEOLOGIC INFORMATION

STATSGO: State Soil Geographic Database

Source: Department of Agriculture, Natural Resources Conservation Services. The U.S. Department of Agriculture's (USDA) Natural Resources Conservation Service (NRCS) leads the national Conservation Soil Survey (NCSS) and is responsible for collecting, storing, maintaining and distributing soil survey information for privately owned lands in the United States. A soil map in a soil survey is a representation of soil patterns in a landscape. Soil maps for STATSGO are compiled by generalizing more detailed (SSURGO) soil survey maps.

SSURGO: Soil Survey Geographic Database

Source: Department of Agriculture, Natural Resources Conservation Services (NRCS)

Telephone: 800-672-5559

SSURGO is the most detailed level of mapping done by the Natural Resources Conservation Services, mapping scales generally range from 1:12,000 to 1:63,360. Field mapping methods using national standards are used to construct the soil maps in the Soil Survey Geographic (SSURGO) database. SSURGO digitizing duplicates the original soil survey maps. This level of mapping is designed for use by landowners, townships and county natural resource planning and management.

APPENDIX C

Facility Employee Interview

The following questions were provided to Mr. Dale Reynolds, an Exide employee at the Frankfort Facility/Site from 1980 through the present. Mr. Reynolds was also provided with Figures 2 and 4 and a draft version of the CCR.

Question: ***Please confirm your dates of employment with Exide and at the Frankfort Facility;***

Response: *Hired by General Battery at the Frankfort facility on 07/07/1980, and have been involved in various capacities at this location since then.*

Question: ***Please describe your level of knowledge of the Site and former Facility operations.***

Response: *Knowledge included the Quality Control areas from 1980 through 1991, then the Material Control areas into 1997, special projects after manufacturing ceased into 1998, when I became the Facility Manager, handling the temporary storage services of the corporation's idle equipment inventory.*

Question: ***Do you have any knowledge of use at the three grassy areas/parcels located outside of the current perimeter fence?***

Response: *Exide owned a house which was rented to an Exide employee located on the lot with the address of 650 Kelley Avenue, which was demolished after manufacturing ceased. Not aware of any specific manufacturing use of the other parcels.*

Question: ***In addition to the nine SWMUs and three AOCs identified on the facility plan, are you aware of any other locations where potential contamination pathways are present? This could include leaking sumps, pits, severely damaged flooring, past spills, tanks, waste storage areas, etc.?***

Response: *Am not aware of other areas where contamination actually occurred, just know of various concrete areas which became significantly corroded.*

Question: ***Are you aware of any locations where lead, acid, battery casings, or other waste materials were spilled, dumped, buried onsite?***

Response: *Please see the response just below for the "yard" question.*

Question: ***For areas of the facility "yard" that are currently paved, are you aware of any sites of spills or materials handling that may have occurred on the ground prior to paving?***

Response: *Before the "yard" was paved, consolidation of returned spent batteries occurred in the yard, and this was probably the "battery loading area" identified in the "1986-1988 Soil Cleanup" section 5.3.2.*

Question: ***Is there currently any problem with trespassers or other members of the general public entering the Site property (albeit without authorization);***

Response: *No current problem is noted; a neighbor child retrieving a stray ball previously reported by a neighbor.*

Question: ***Are you aware of any current or former gasoline filling stations in the immediate vicinity of the Site and/or across the street from the property at 1403 Washington Avenue? If so, please describe the approximate location.***

Response: *Do not recall noticing any gasoline filling stations in the immediate vicinity. Do not know whether or not Wampler's has a fuel tank for filling their own equipment.*

Question: ***During the removal of UST-2 do you recall observing any remnants of an additional UST on the north side of the removal area?***

Response: *Do not recall observing any remnants of an additional UST.*

Question*:** ***Are you aware of any usage of chlorinated solvents onsite? This includes compounds such as tetrachloroethylene, commonly referred to as PCE; and trichloroethylene, commonly referred to as TCE. Both are also described as "dry cleaning fluid" and both are most often used industrially as degreasing compounds. If you are aware of the use of chlorinated solvents onsite - how were they managed as a waste?

Response: *None, to my knowledge, the materials department did not order any of this type material.*

Question: ***Please confirm the date/year when the new formation building was constructed. Was the underlying area paved prior to construction of the building?***

Response: *Believe this area was enclosed in the late 1980's, and it was initially used for material storage. A few years later the "New Formation" was set up in this area. Before this area was enclosed, a number of fiberglass tanks, for the mixing of acid, were located in this area, with a concrete containment system below the tanks. Do not believe the remainder of this area was paved until it was enclosed.*

Question: ***Can you describe the approximate dimensions, capacity, and materials of construction of the former sludge holding tank (SWMU-2).***

Response: *SWMU-2 was a round fiberglass tank approximately 12' diameter and 12' tall which contained large high speed mixer blades for agitation of the sludge material.*

Question: ***To your knowledge were there ever any wells operated onsite for water production?***

Response: *Have no knowledge of water well usage.*

To: LEMASTERS, GREGG
Subject: RE: wellhead proximity

Mr. Lemasters,

Thank you for sending me the findings of your well head proximity review for the property at 555 north hoke avenue in Frankfort, Indiana. The letter indicates that the reference location is within a WHPA. However, when I used the IDEM WHPA online tool it indicated that the location was not in a WHPA. Please see attached screenshot. Which source of information takes precedence?
